*Some*  
^ **Highlights from the STAR Experimental Program  
at RHIC**

**Jim Thomas**  
**Lawrence Berkeley National Laboratory**  
**for the STAR Collaboration**

**ICHEP Amsterdam**  
**July 27<sup>th</sup>, 2002**

# The RHIC Accelerator Facility

## RHIC

- Two independent accelerator rings
- 3.83 km in circumference
- Accelerates everything, from p to Au

	$\sqrt{s}$	L
p-p	500	$10^{32}$
Au-Au	200	$10^{26}$
	GeV	$\text{cm}^{-2} \text{s}^{-1}$

- Polarized protons
- STAR is the *Hadronic Signals* experiment
- At its heart is a large  
Time  
Projection  
Chamber

# The STAR Detector at RHIC

**STAR uses the world's largest Time Projection Chamber**

# Au on Au Event at CM Energy 130 GeV\*A

# Au on Au Event at CM Energy 130 GeV\*A

# Spectra Measured .vs. Centrality (impact parameter)

Peripheral Collision

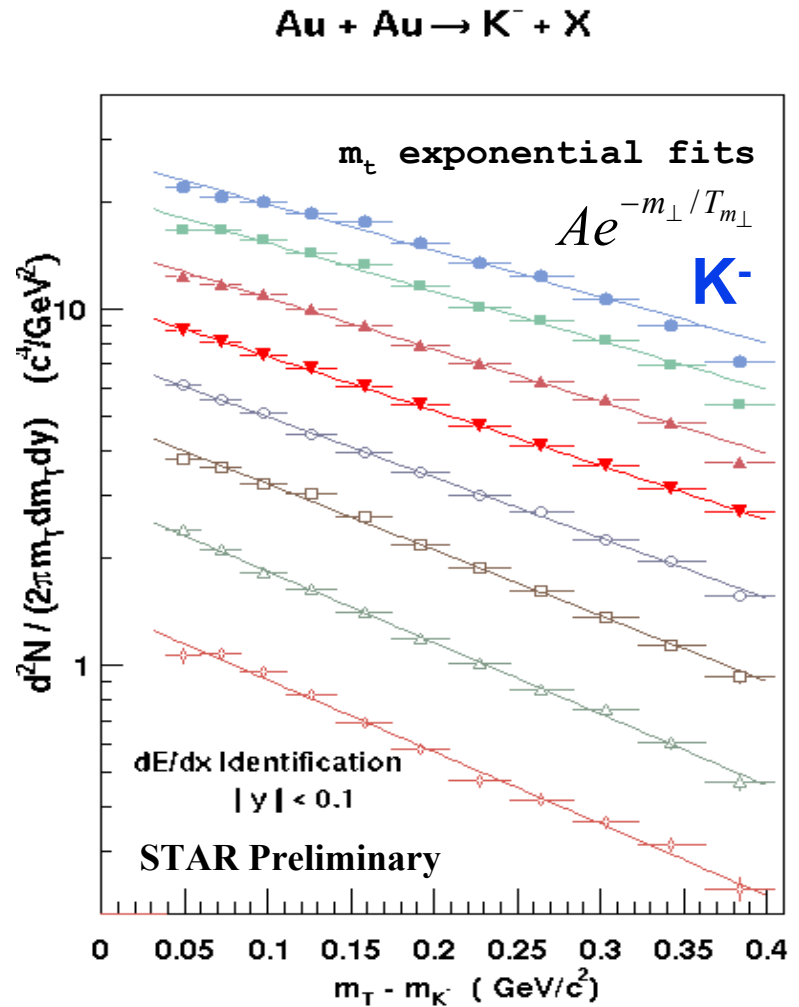

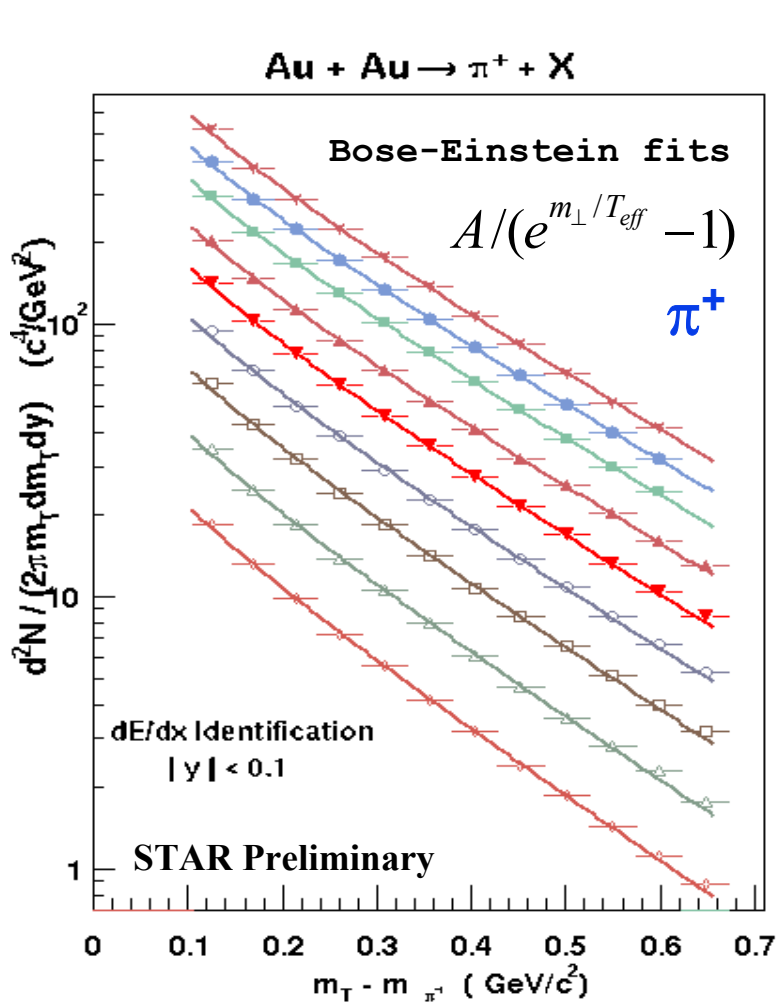

(near) Central Collision

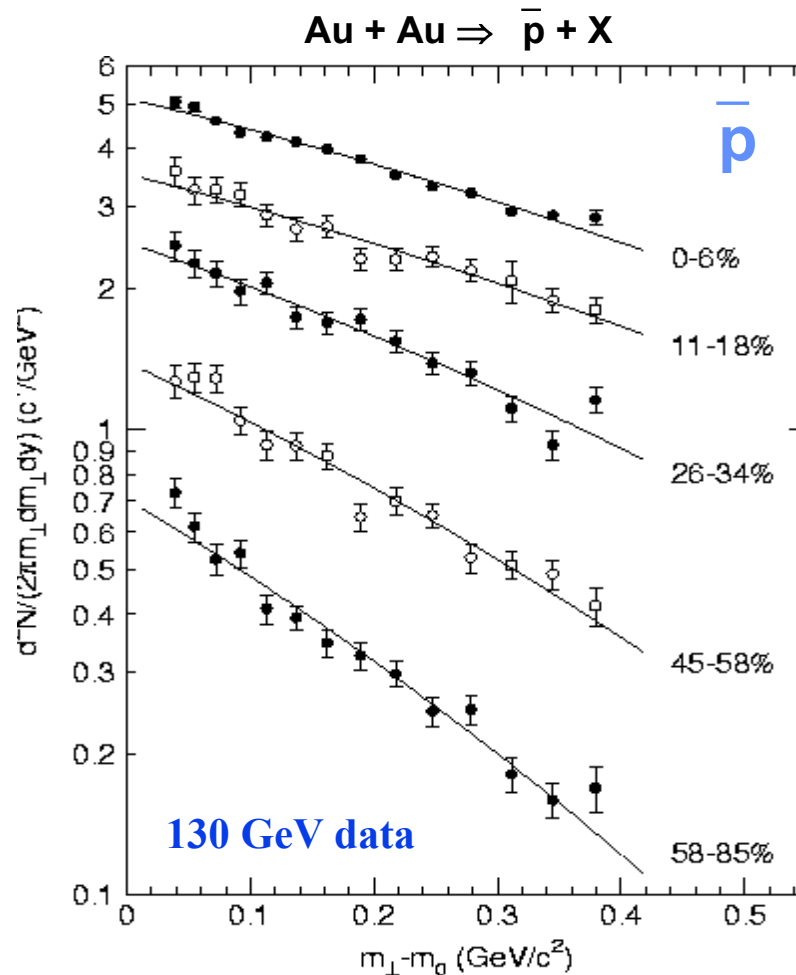

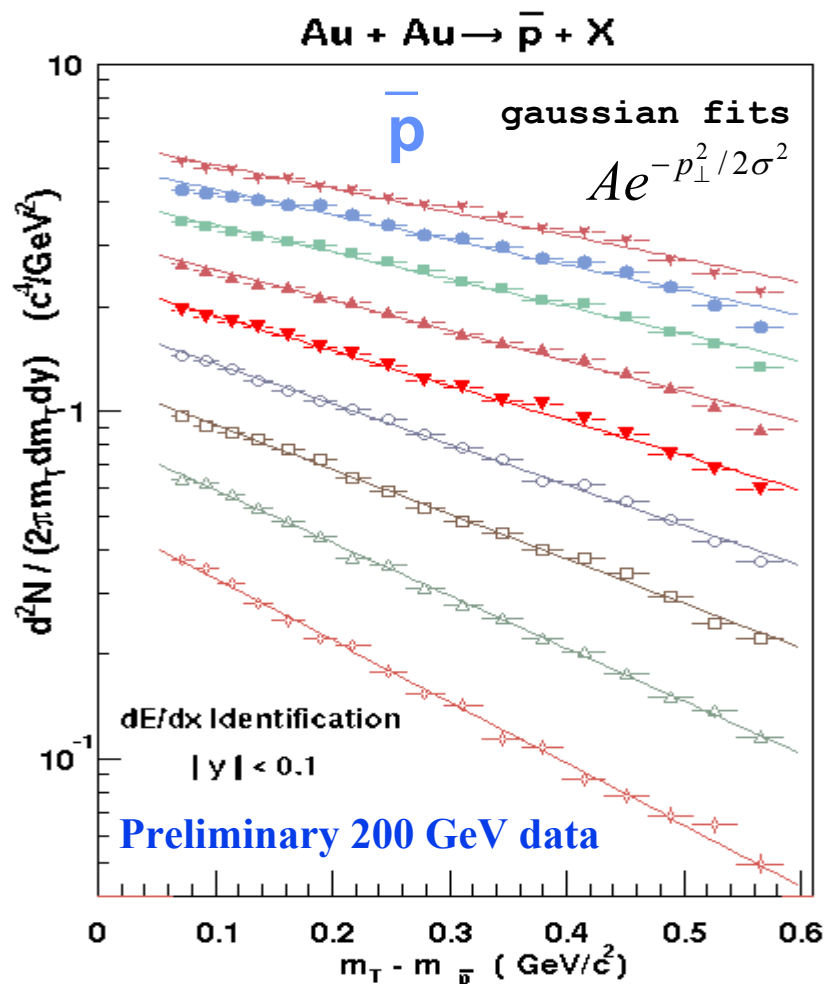

central collision  $\Rightarrow$  high multiplicity in CTB & low multiplicity in Zcal

# What's New? Identified Particle Spectra at 200 GeV

**$\pi^+, \pi^-, K^+, K^-$  spectra versus centrality  
 ( 130 GeV/N data in *nucl-ex/0206008* )**

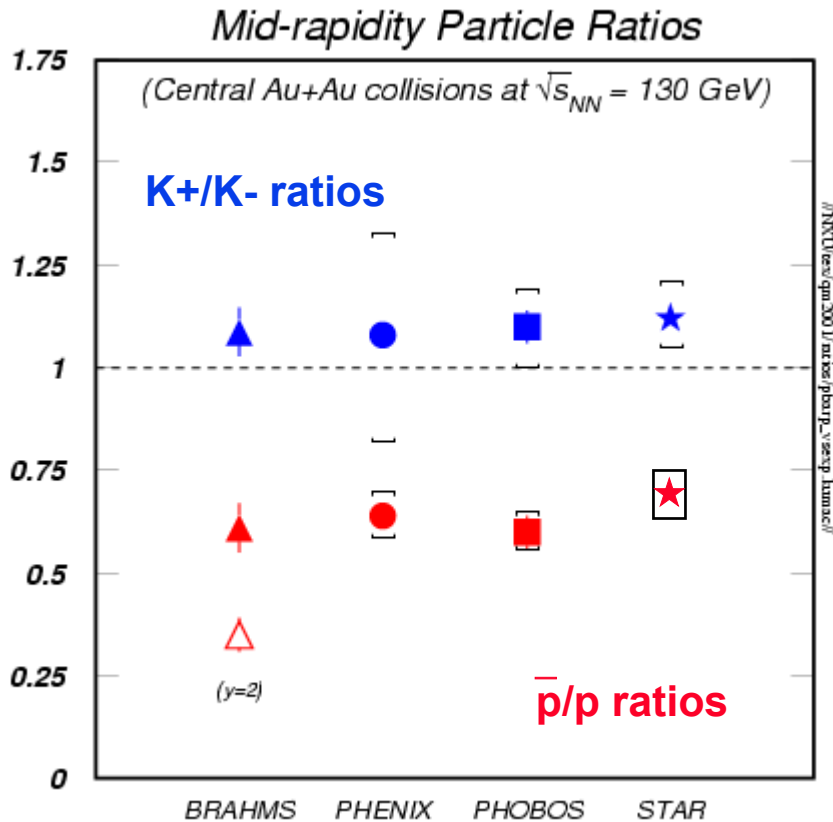

# Anti-Proton Spectra at 200 & 130 GeV / N

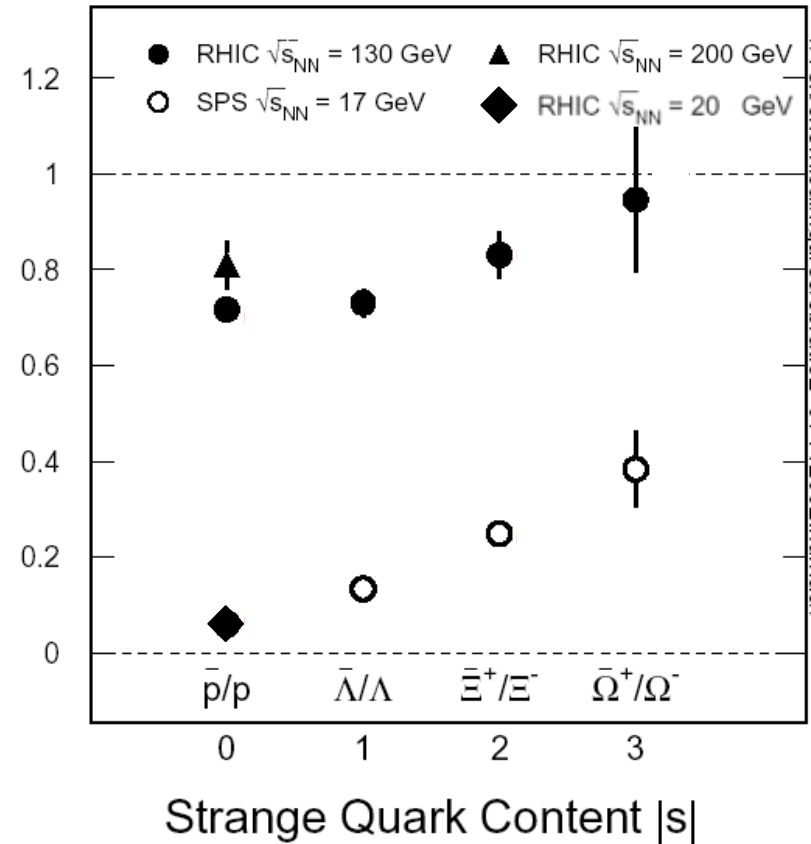

**p and  $\bar{p}$  spectra versus centrality  
[ 130 GeV data in PRL 87 (2002) ]**

# Anti-Particle to Particle Ratios

Baryon Ratios

Excellent agreement between experiments at  $y = 0$ ,  $\sqrt{s} = 130$

## STAR results on the $\bar{p}/p$ ratio

- $\bar{p}/p = 0.11 \pm 0.01$  @ 20 GeV
- $\bar{p}/p = 0.71 \pm 0.05$  @ 130 GeV
  - Previously reported as  $0.60 \pm 0.06$
- $\bar{p}/p = 0.80 \pm 0.05$  @ 200 GeV

# Anti-Baryon/Baryon Ratios versus $\sqrt{s}_{NN}$

In the early universe

- $\bar{p}/p$  ratio = 0.999999

At RHIC, pair-production increases with  $\sqrt{s}$

Mid-rapidity region is not yet yet baryon-free!

$$\frac{Y_{pbar}}{Y_p} = \frac{Y_{pair}}{Y_{pair} + Y_{Trans}} \approx 0.8$$

Pair production is larger than baryon transport

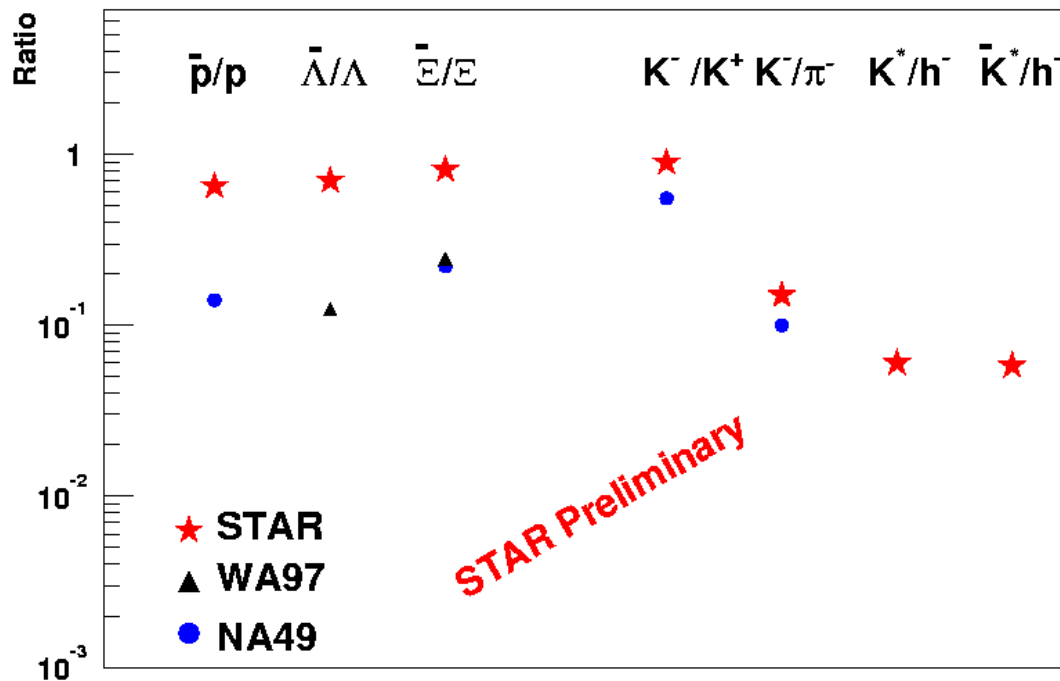

$$\frac{Y_{pair}}{Y_{Tr}} \approx 4$$

80% of protons from pair production

- 20% from initial baryon number transported over 5 units of rapidity

In HI collisions at RHIC, more baryons are **pair produced** than are brought in by the initial state

# Particle Ratios at RHIC

$$\begin{aligned} \bar{p}/p &= 0.71 \pm 0.02(\text{stat}) \pm 0.05(\text{sys}) \\ &= 0.60 \pm 0.04(\text{stat}) \pm 0.06(\text{sys}) \\ &= 0.64 \pm 0.01(\text{stat}) \pm 0.07(\text{sys}) \\ &= 0.64 \pm 0.04(\text{stat}) \pm 0.06(\text{sys}) \\ \bar{\Lambda}/\Lambda &= 0.73 \pm 0.03(\text{stat}) \\ \bar{\Xi}^+/\bar{\Xi}^- &= 0.83 \pm 0.03(\text{stat.}) \pm 0.05(\text{sys.}) \\ K^-/\pi^- &= 0.15 \pm 0.01(\text{stat}) \pm 0.02(\text{sys}) \\ K^+/\pi^+ &= 0.16 \pm 0.01(\text{stat}) \pm 0.02(\text{sys}) \\ \pi^+/\pi^- &= 1.00 \pm 0.01(\text{stat}) \pm 0.02(\text{sys}) \\ &= 0.95 \pm 0.03(\text{stat}) \pm 0.05(\text{sys}) \end{aligned}$$

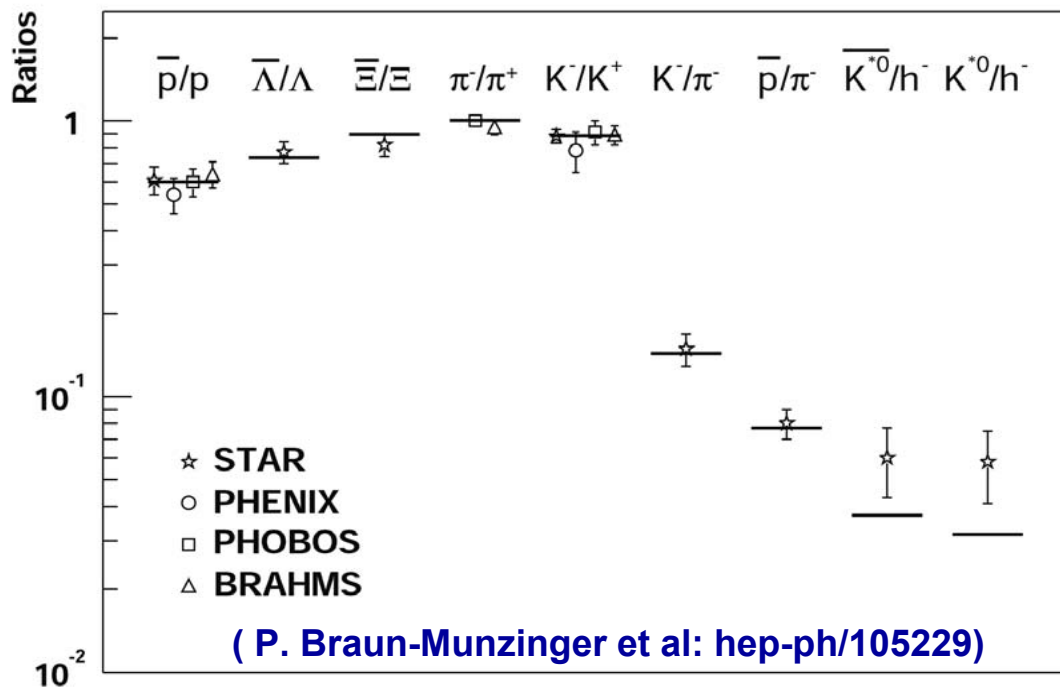

$$\begin{aligned} K^-/K^+ &= 0.89 \pm 0.008(\text{stat}) \pm 0.05(\text{sys}) \\ &= 0.91 \pm 0.07(\text{stat}) \pm 0.06(\text{sys}) \\ &= 0.89 \pm 0.07(\text{stat}) \pm 0.05(\text{sys}) \\ K^+/K^- &= 1.08 \pm 0.03(\text{stat}) \pm 0.22(\text{sys}) \text{ min. bias} \\ K^-/\pi^- &= 0.15 \pm 0.01(\text{stat}) \pm 0.02(\text{sys}) \\ K^+/\pi^+ &= 0.16 \pm 0.01(\text{stat}) \pm 0.02(\text{sys}) \\ \bar{K}^*/K^* &= 0.92 \pm 0.14(\text{stat.}) \end{aligned}$$

$$\begin{aligned} \phi/h^- &= 0.021 \pm 0.001(\text{stat}) \pm 0.005(\text{sys}) \\ \Lambda/h^- &= 0.060 \pm 0.001(\text{stat}) \pm 0.006(\text{sys}) \\ \bar{\Lambda}/h^- &= 0.043 \pm 0.001(\text{stat}) \pm 0.004(\text{sys}) \\ K_s^0/h^- &= 0.124 \pm 0.001(\text{stat}) \\ (\bar{K}^*+K^*)/2h^- &= 0.032 \pm 0.003(\text{stat.}) \pm 0.008(\text{sys.}) \\ 2\phi/(\bar{K}^*+K^*) &= 0.64 \pm 0.06(\text{stat}) \pm 0.16(\text{sys}) \end{aligned}$$

Good agreement between the 4 experiments STAR, PHOBOS, PHENIX, BRAHMS

# Chemical Freeze-out – from a thermal model

## Thermal model fits

$$T_{\text{ch}}(\text{RHIC}) = 175 \pm 7 \text{ MeV}$$

$$\mu_{\text{B}}(\text{RHIC}) = 51 \pm 6 \text{ MeV}$$

$$T_{\text{ch}}(\text{SPS}) = 160 - 170 \text{ MeV}$$

$$\mu_{\text{B}}(\text{SPS}) \cong 270 \text{ MeV}$$

## Compare to QCD on Lattice:

$$T_{\text{c}} = 154 \pm 8 \text{ MeV} \quad (N_{\text{f}}=3)$$

$$T_{\text{c}} = 173 \pm 8 \text{ MeV} \quad (N_{\text{f}}=2)$$

(ref. Karsch QM01)

### Assume:

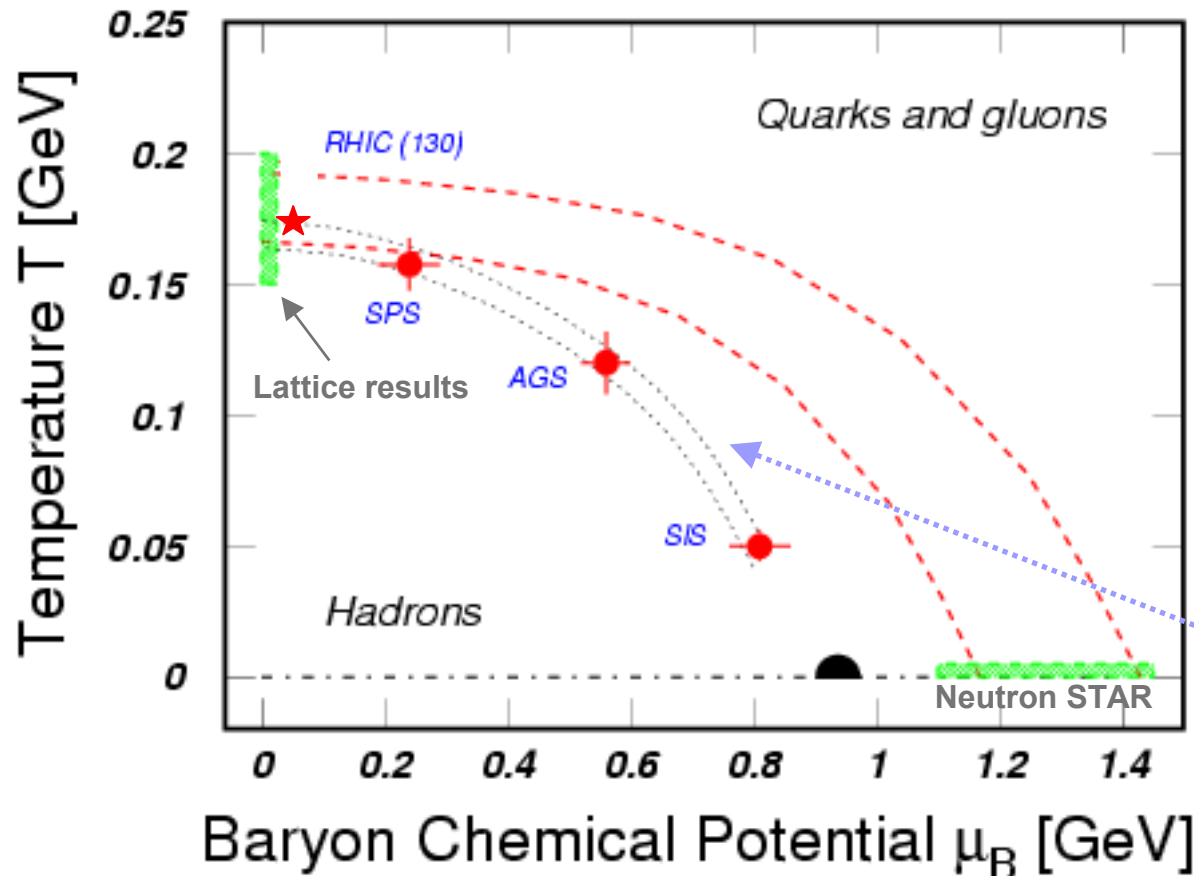

- Thermally and chemically **equilibrated** fireball at hadro-chemical freeze-out
- Law of mass action is applicable

### Recipe:

- Grand canonical ensemble to describe partition function  $\Rightarrow$  density of particles of species  $\rho_i$
- Fixed by constraints: Volume  $V$ , strangeness chemical potential  $\mu_{\text{S}}$ , and isospin

**input: measured particle ratios**    **output: temperature  $T$  and baryo-chemical potential  $\mu_{\text{B}}$**

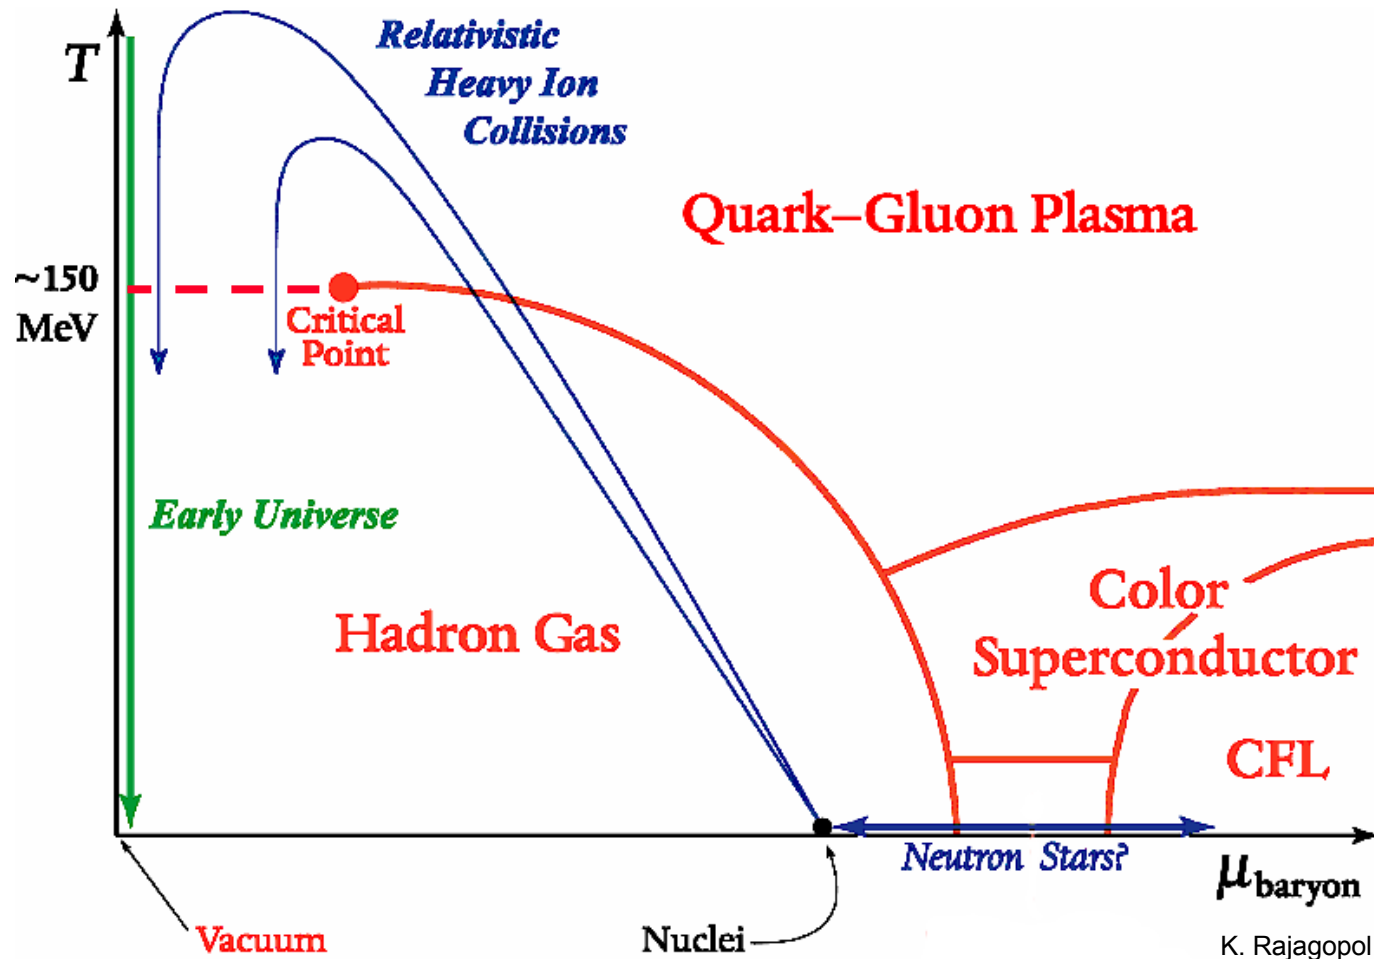

# Putting STAR on the Phase Diagram

- Final-state analysis suggests RHIC reaches the phase boundary
- Hadron resonance ideal gas (M. Kaneta and N. Xu, nucl-ex/0104021 & QM02)
  - $T_{CH} = 175 \pm 10 \text{ MeV}$
  - $\mu_B = 40 \pm 10 \text{ MeV}$
- $\langle E \rangle / N \sim 1 \text{ GeV}$  (J. Cleymans and K. Redlich, Phys.Rev.C, 60, 054908, 1999 )

We know where we are on the phase diagram but now we want to know what other features are on the diagram

# The Phase Diagram for Nuclear Matter

The goal is to explore nuclear matter under extreme extreme conditions -  $T > m_{\pi} c^2$  and  $\rho > 10 * \rho_0$

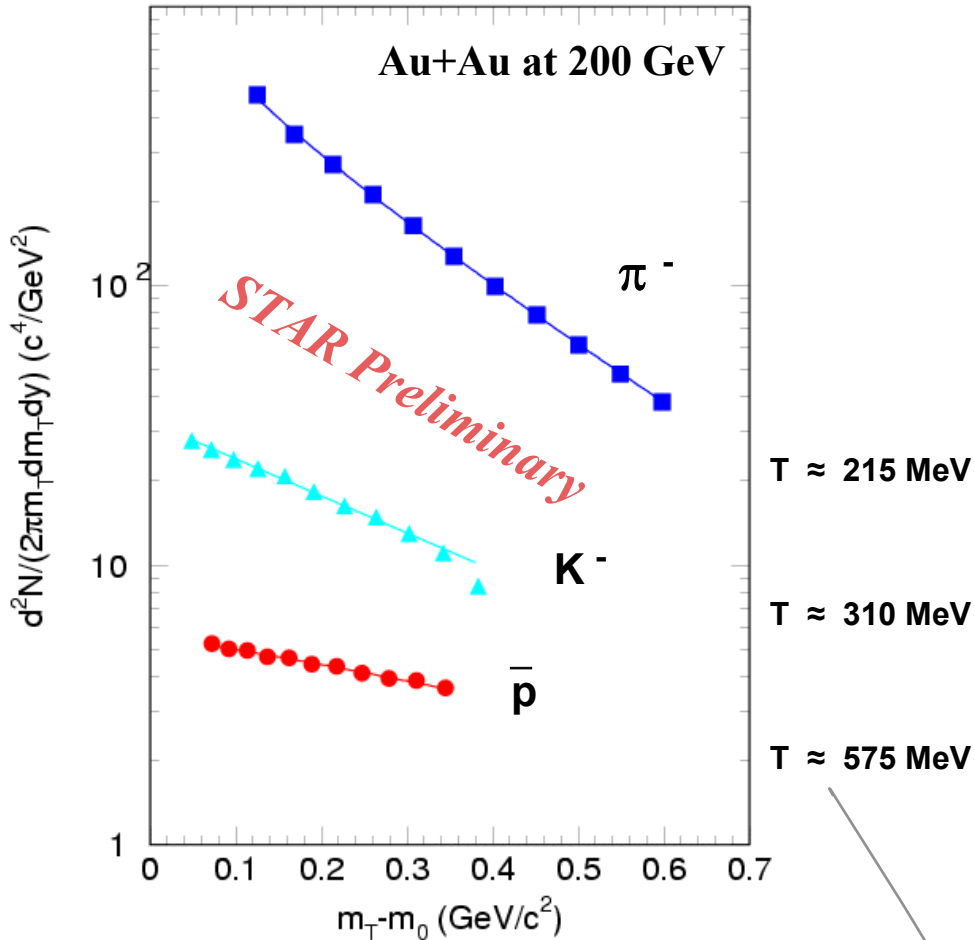

# Chemical and Kinetic Freeze-out

- **Chemical freeze-out (first)**
  - End of **inelastic** interactions
  - Number of each particle species is frozen
- **Useful data**
  - Particle ratios
- **Kinetic freeze-out (later)**
  - End of **elastic** interactions
  - Particle momenta are frozen
- **Useful data**
  - Transverse momentum distributions
  - and Effective temperatures

# Transverse Flow

Slopes decrease with mass.  $\langle p_T \rangle$   
 $\langle p_T \rangle$  and the effective temperature  
 increase with mass.

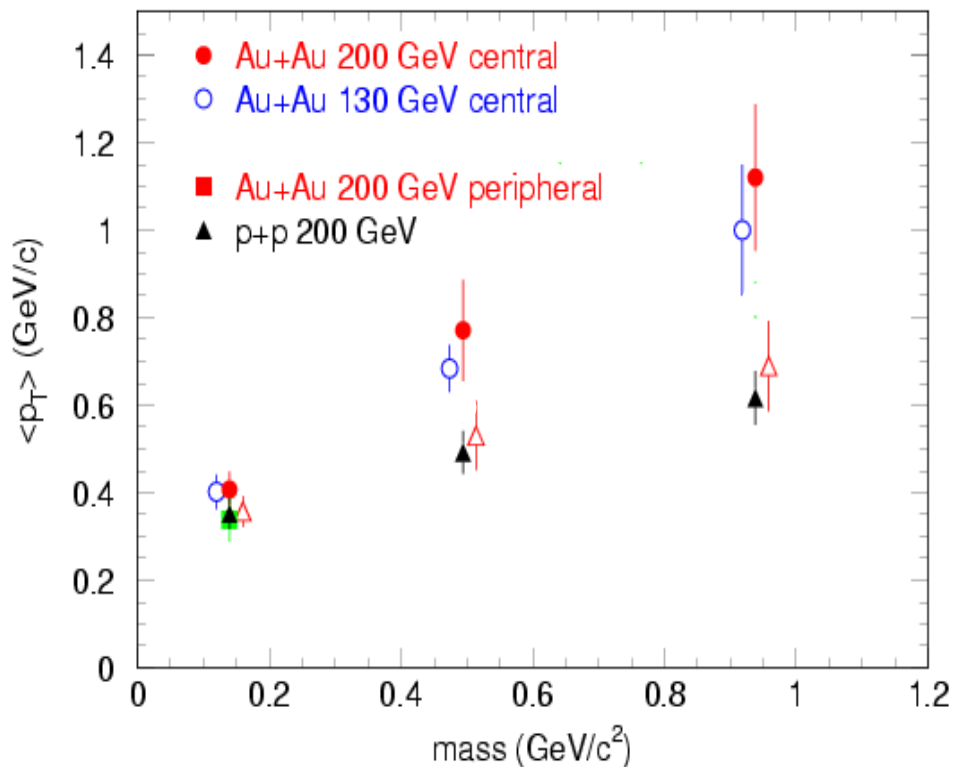

The transverse radial expansion  
 of the source (flow) adds kinetic  
 energy to the particle distribution.  
 So the classical expression for  
 $E_{Tot}$

$$\bar{E} = \frac{3}{2}T + \frac{1}{2}mv^2$$

suggests a linear relationship

$$T_{Obs} = T_{KFO} + mass \times \bar{\beta}^2$$

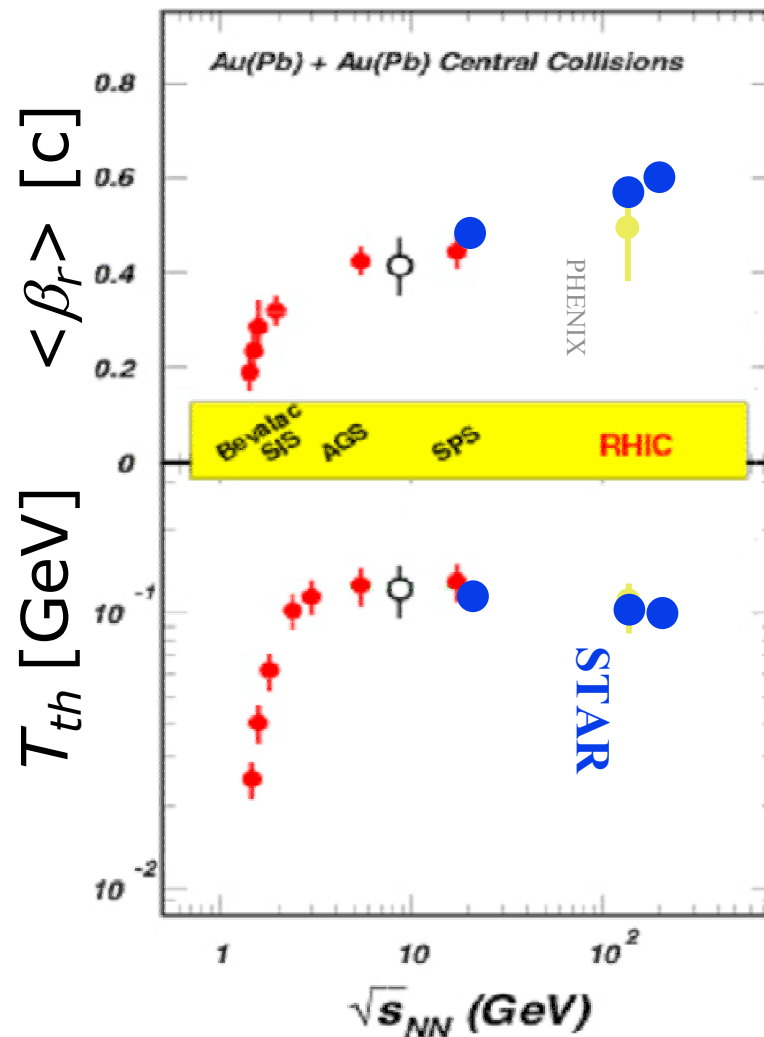

# Kinetic Freezeout from Transverse Flow

$$\langle \beta_r \rangle \text{ (RHIC)} = 0.55 \pm 0.1 c$$

$$T_{\text{KFO}} \text{ (RHIC)} = 100 \pm 10 \text{ MeV}$$

Thermal freeze-out determinations are done with the blast-wave model to find  $\langle p_T \rangle$

Explosive Transverse Expansion at RHIC  $\Rightarrow$  High Pressure

# Anisotropic (Elliptic) Transverse Flow

Peripheral Collisions

Anisotropic Flow

- The overlap region in peripheral collisions is is not symmetric in coordinate space
  - Almond shaped overlap region
    - Easier for particles to emerge in the direction of x-z plane
    - Larger area shines to the side
  - Spatial anisotropy → Momentum anisotropy
    - Interactions among constituents generates a pressure gradient which transforms the initial initial spatial anisotropy into the observed momentum anisotropy
  
- Perform a Fourier decomposition of the momentum space particle distributions in the x-y plane
  - $v_2$  is the 2<sup>nd</sup> harmonic Fourier coefficient of the distribution of particles with respect to the reaction plane

$$v_2 = \langle \cos 2\phi \rangle \quad \phi = \text{atan} \frac{p_y}{p_x}$$

# $v_2$ vs. Centrality

**Anisotropic transverse flow is large at RHIC**

- $v_2$  is large
  - 6% in peripheral collisions
  - Smaller for central collisions
- Hydro calculations are in reasonable agreement with the data
  - In contrast to lower collision energies where hydro over-predicts anisotropic flow
- Anisotropic flow is developed by rescattering
  - Data suggests early time history
  - Quenched at later times

# $v_2$ vs. $p_T$ and Particle Mass

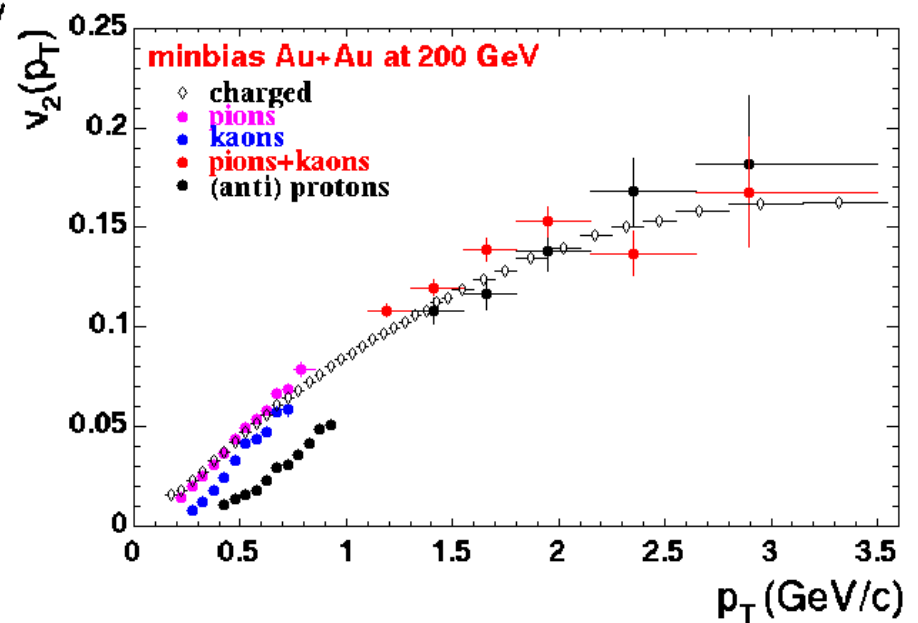

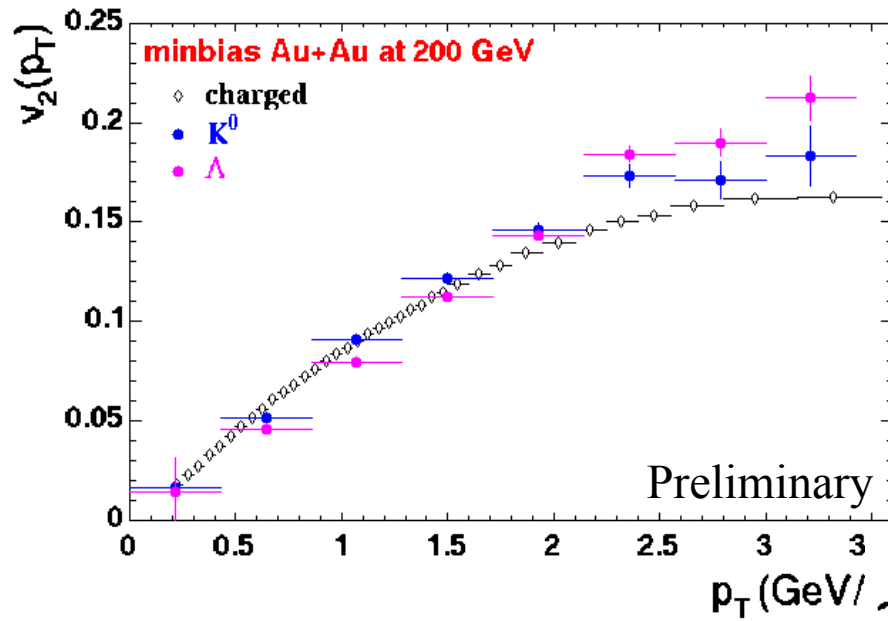

- The mass dependence is reproduced by hydrodynamic models
  - Hydro assumes local thermal equilibrium
  - At early times
  - Followed by hydrodynamic expansion

**Hydro does a surprisingly good job!**

D. Teaney et al., QM2001 Proc.  
P. Huovinen et al., nucl-th/0104020

# $v_2$ for $\pi$ , $K$ , $K^0$ , $\bar{p}$ and $\Lambda$

# $v_2$ for High $p_t$ Particles

See also, M. Gyulassy, I. Vitev and X.N. Wang, nucl-th/00012092

$v_2$  is large ... but at  $p_t > 2$  GeV/c the data starts to deviate from hydrodynamics

# Centrality Dependence of $v_2(p_T)$

- $v_2$  is saturated at high  $p_T$  and it does not come back down as rapidly as expected
- What does  $v_2$  do at very high  $p_T$ ?

# $v_2$ up to 12 GeV/c

$v_2$  remains saturated

# Hard Probes in Heavy-Ion Collisions

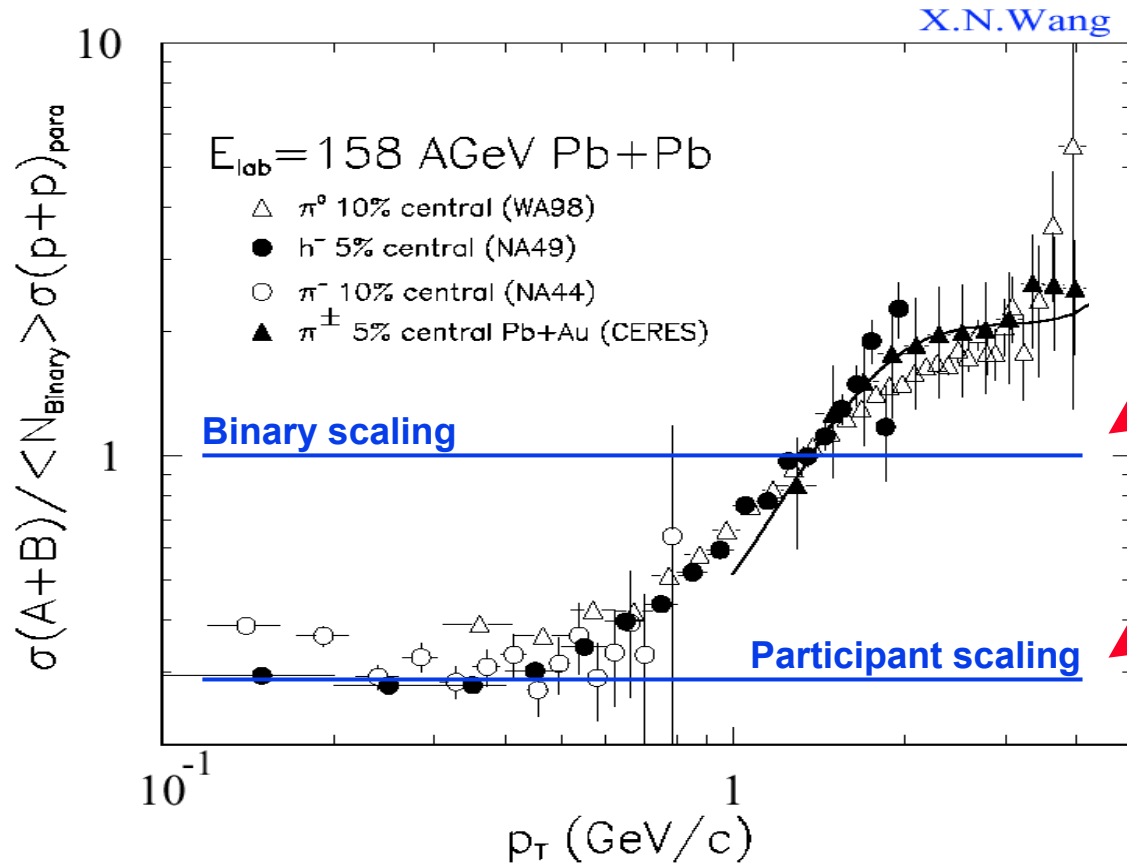

- New opportunity using Heavy Ions at RHIC → Hard Parton Scattering
  - $\sqrt{s_{NN}} = 200$  GeV at RHIC
  - 17 GeV at CERN SPS
- Jets and mini-jets
  - 30-50 % of particle production
  - High  $p_t$  leading particles
  - Azimuthal correlations
- Extend into perturbative regime
  - Calculations reliable (?)
- Scattered partons propagate through matter & radiate energy ( $dE/dx \sim x$ ) in colored medium
  - Interaction of parton with partonic matter
  - Suppression of high  $p_t$  particles “jet quenching”
  - Suppression of angular correlations

# Scaling pp to AA ... including the Cronin Effect Effect

**At SPS energies:**

- High  $p_t$  spectra evolves systematically from pp  $\rightarrow$  pA  $\rightarrow$  AA
- Hard scattering processes scale with the number of binary collisions
- Soft scattering processes scale with the number of participants
- The ratio exhibits "Cronin effect" behavior at the SPS
- No need to invoke QCD energy loss

$$\frac{\text{Yield}_{\text{central}} / \langle N_{\text{binary}} \rangle_{\text{central}}}{\text{Yield}_{\text{pp}}} > 1$$

# Inclusive $p_T$ Distribution of Hadrons at 200 GeV

- Scale Au-Au data by the number of binary collisions
- Compare to UA1  $\bar{p}p$  reference data measured at 200 GeV

# Comparison of Au+Au / p+p at 130 GeV

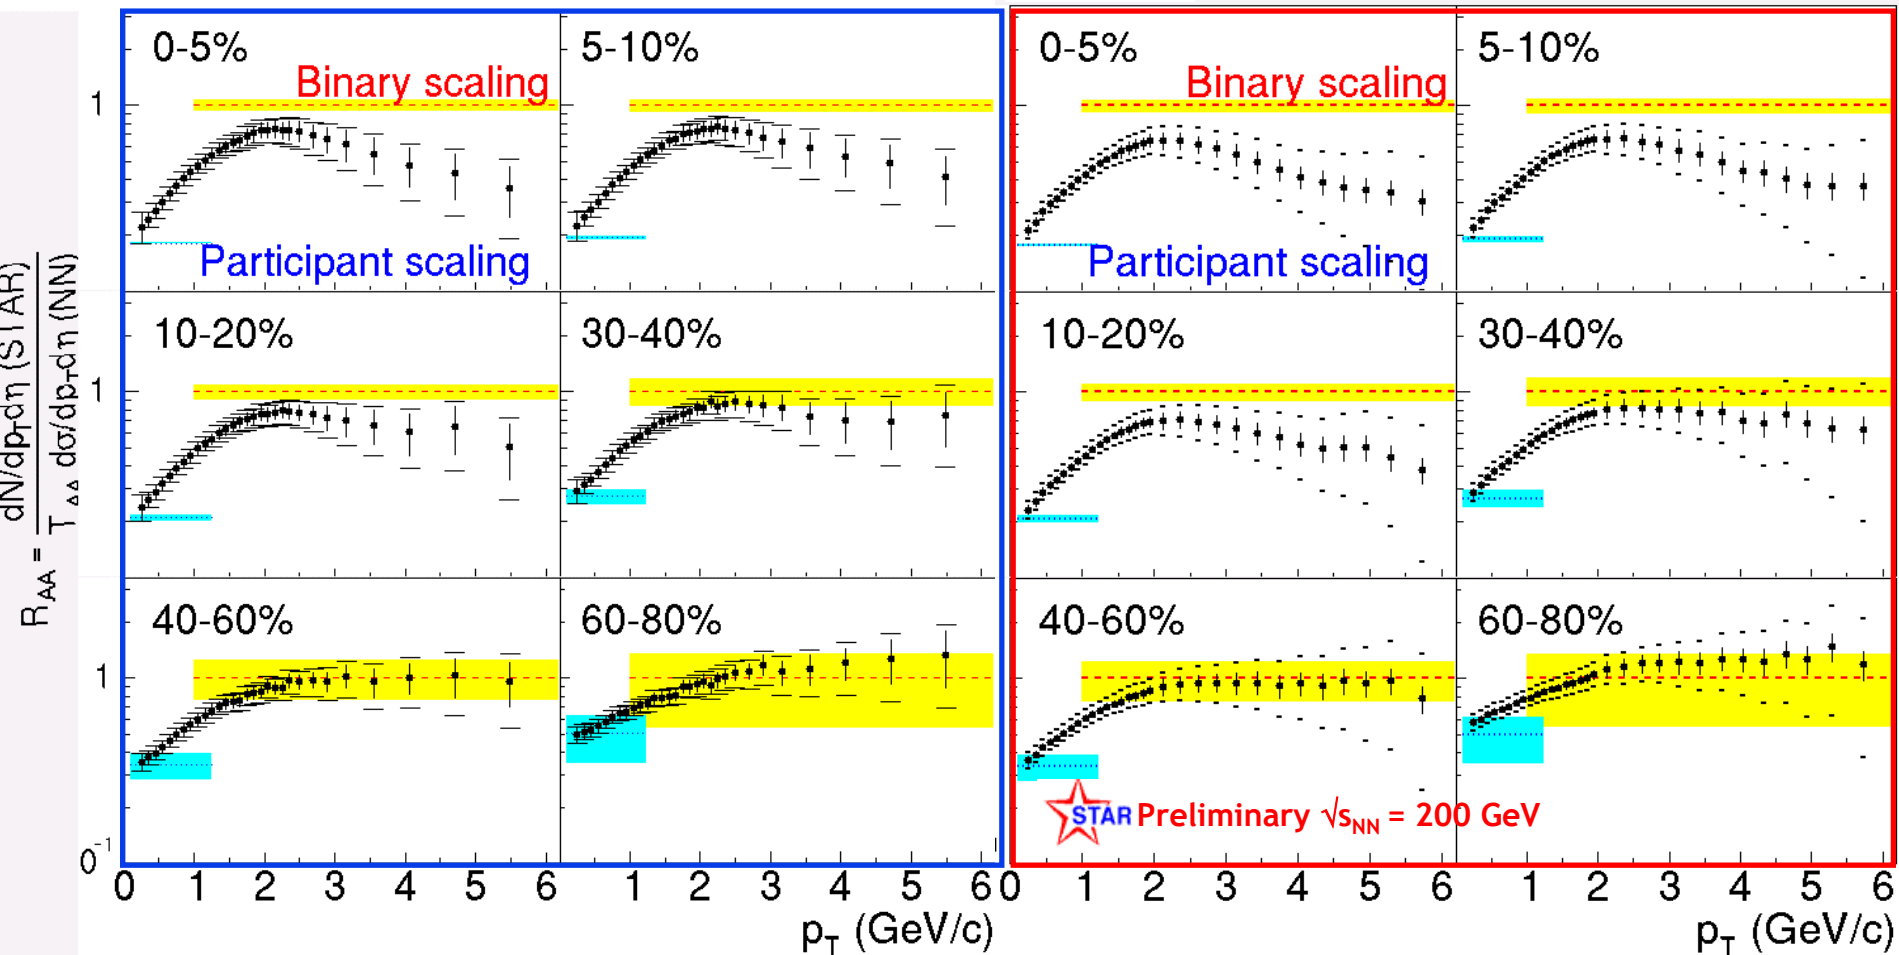

# $R_{AA}$ Comparison to $p_T = 6$ GeV/c

130 GeV nucl-ex/0206011

STAR Preliminary  $\sqrt{s_{NN}} = 200$  GeV

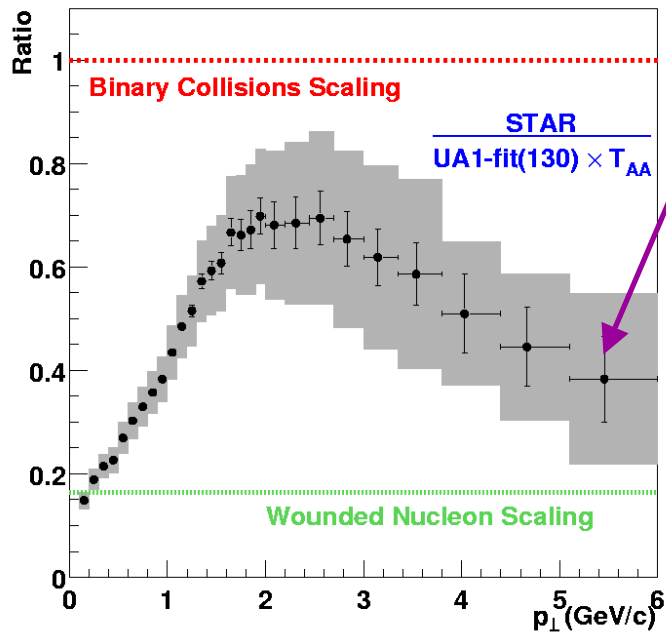

Similar Suppression at high  $p_T$  in 130 and 200 GeV data

# Flow vs. Inclusive Hadron Spectra

Different views of same physics?

Evidence for hadron suppression at high  $p_T$

Partonic interaction with matter?  $dE/dx$ ?

# Jet Physics ... it is easier to find one in $e^+e^-$

## Jet event in $e^+e^-$ collision

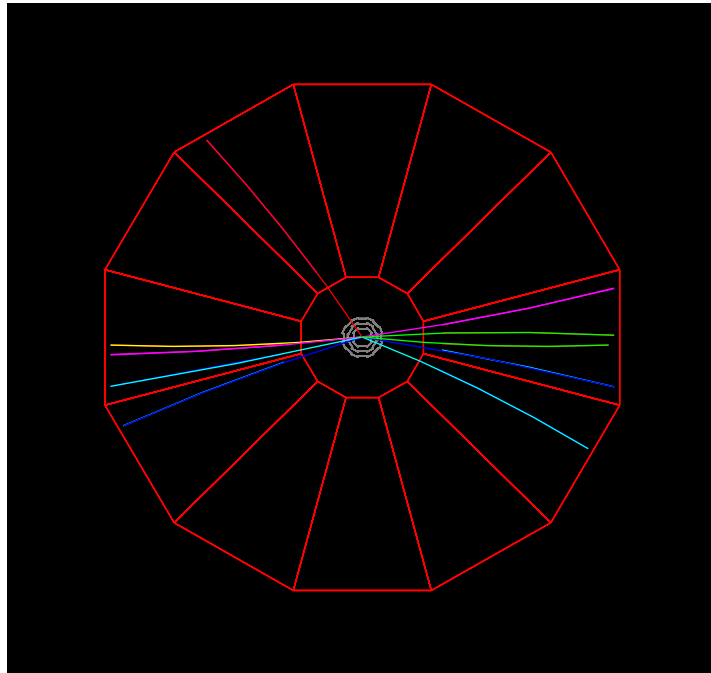

## STAR Au+Au collision

# Identifying jets on a *statistical* basis in Au-Au

- You can see the jets in p-p data at RHIC

- Identify jets on a *statistical* basis in Au-Au
- Given a trigger particle with  $p_T > p_T(\text{trigger})$ , associate particles with  $p_T > p_T(\text{associated})$

$$C_2(\Delta\phi, \Delta\eta) = \frac{1}{N_{TRIGGER}} \frac{1}{\text{Efficiency}} N(\Delta\phi, \Delta\eta)$$

STAR Preliminary  
 Au+Au @ 200 GeV/c  
 0-5% most central  
 $4 < p_T(\text{trig}) < 6 \text{ GeV/c}$   
 $2 < p_T(\text{assoc.}) < p_T(\text{trig})$

# Peripheral Au+Au data vs. pp+flow

$$C_2(Au+Au) = C_2(p+p) + A * (1 + 2v_2^2 \cos(2\Delta\phi))$$

Ansatz:

A high  $p_T$  triggered Au+Au event is a superposition of a high  $p_T$  triggered p+p event plus anisotropic transverse flow

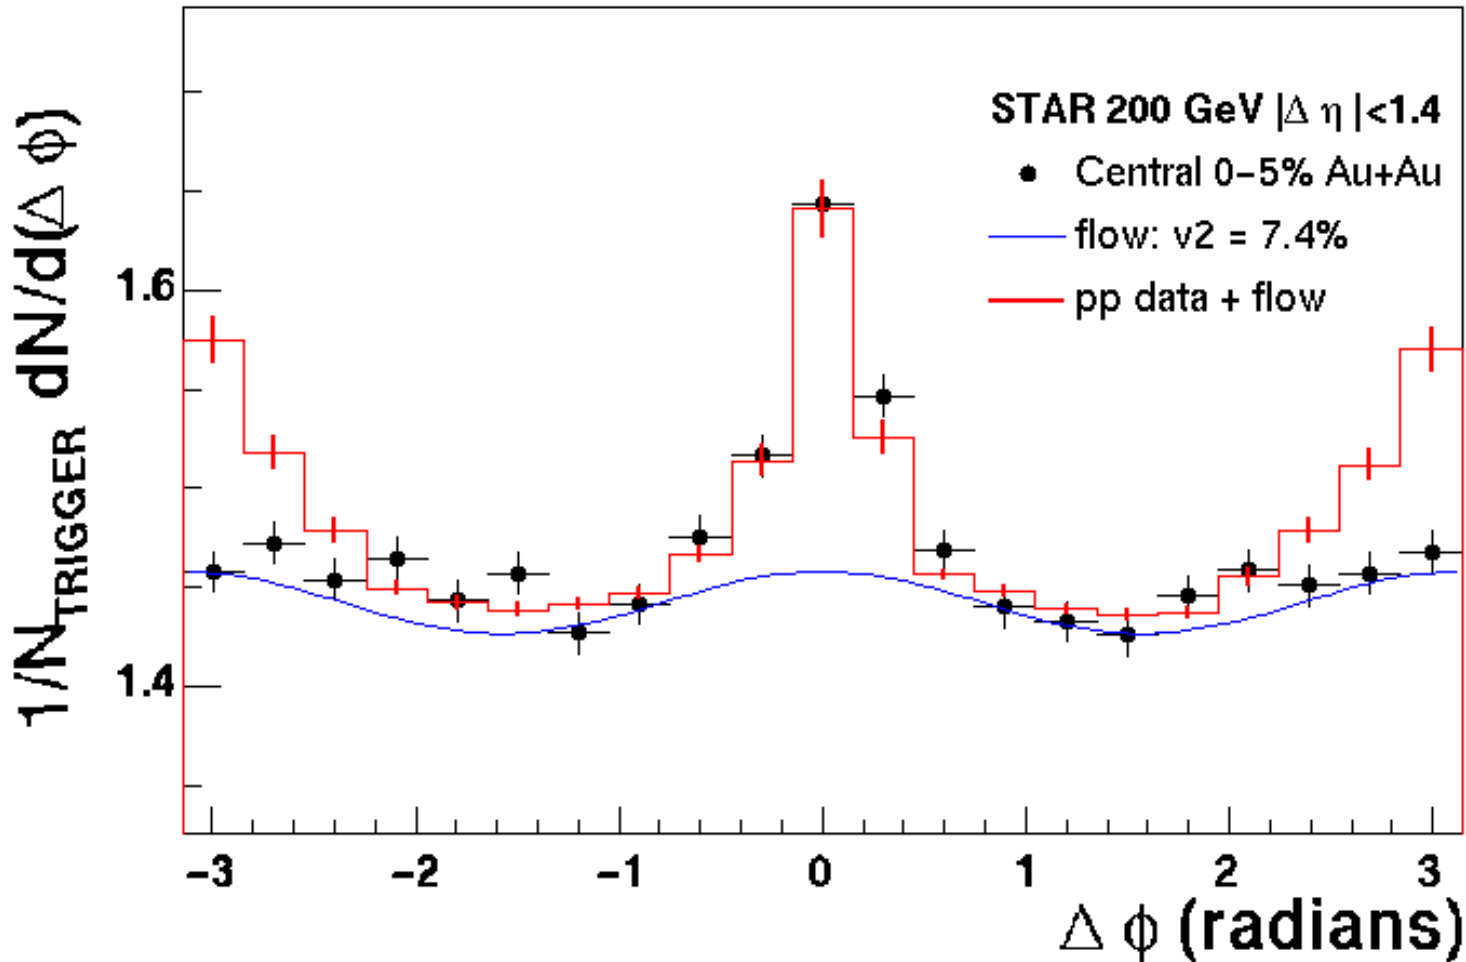

$v_2$  from reaction plane analysis

“A” is fit in non-jet region ( $0.75 < |\Delta\phi| < 2.24$ )

# Central Au+Au data vs. pp+flow

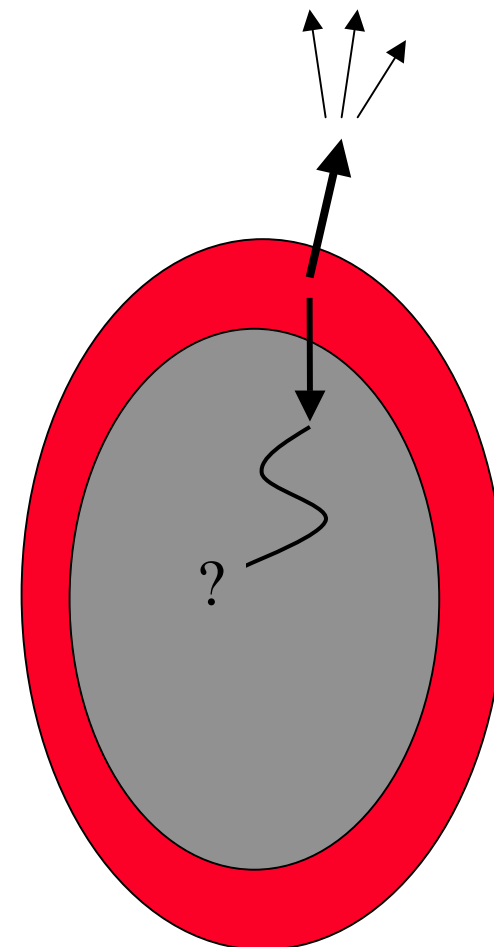

$$C_2(Au+Au) = C_2(p+p) + A * (1 + 2v_2^2 \cos(2\Delta\phi))$$

- The backward going jet is missing in central Au-Au collisions when compared to p-p data + flow
- Other features of the data
  - High  $p_T$  charged hadrons dominated by jet fragments
    - Relative charge
    - Azimuthal correlation width
    - Evolution of jet cone azimuthal correlation strength with centrality
- Other explanations for the disappearance of back-to-back correlations in central Au-Au?
  - Investigate nuclear  $k_T$  effects
    - Experiment: p+Au or d+Au
    - Theory: Add realistic nuclear  $k_T$  to the models

Surface emission?

Suppression of back-to-back correlations in central Au+Au collisions

# Conclusions About Nuclear Matter at RHIC

---

- **Its hot**
  - Chemical freeze out at 175 MeV
  - Thermal freeze out at 100 MeV
  - The universal freeze out temperatures are surprisingly flat as a function of  $\sqrt{s}$
- **Its fast**
  - Transverse expansion with an average velocity of 0.55 c
  - Large amounts of anisotropic flow ( $v_2$ ) suggest hydrodynamic expansion and high pressure at early times in the collision history
- **Its opaque**
  - Saturation of  $v_2$  at high  $p_T$
  - Suppression of high  $p_T$  particle yields relative to p-p
  - Suppression of the away side jet
- **And its nearly in thermal equilibrium**
  - Excellent fits to particle ratio data with equilibrium thermal models
  - Excellent fits to flow data with hydrodynamic models that assume equilibrated systems
