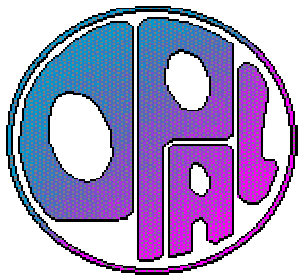
Abstract 376



Isolated Prompt Photon Production in Photon-Photon Collisions at $\sqrt{s_{ee}}$=183-209 GeV

T. Schörner-Sadenius

on behalf of the OPAL Collaboration

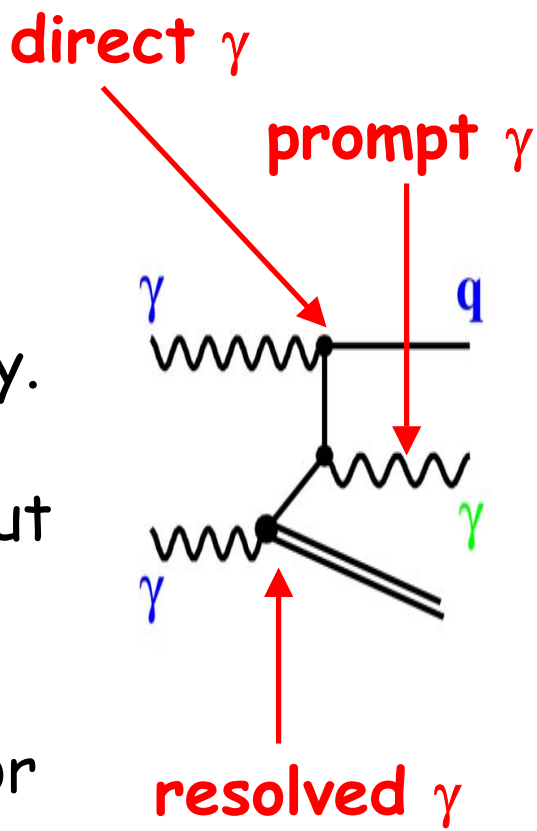
ICHEP 2002, Amsterdam

23-31 July 2002

'Prompt' ≡ not coming from particle decays/fragmentation, but emitted from the hard underlying scattering.

Prompt Photons in $\gamma\gamma \rightarrow \gamma + X$

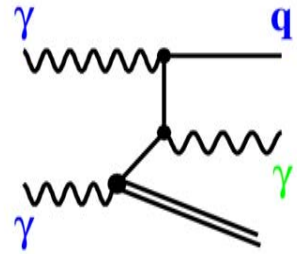
- Allow to study photon's hadronic structure and test QCD predictions:
  - Prompt γ appear in resolved processes (in LO; in NLO also in direct events).
  - Small NLO corrections / scale dependency.
  - 'Cleaner' than dijets (hadrons, D*)
    ➔ less uncertainty from hadronisation (but prompt γ have smaller Xsection ~$O(\alpha_{EM})$).
- Might further be used for
  - studies of the underlying parton picture or
  - background studies in LHC Higgs searches.



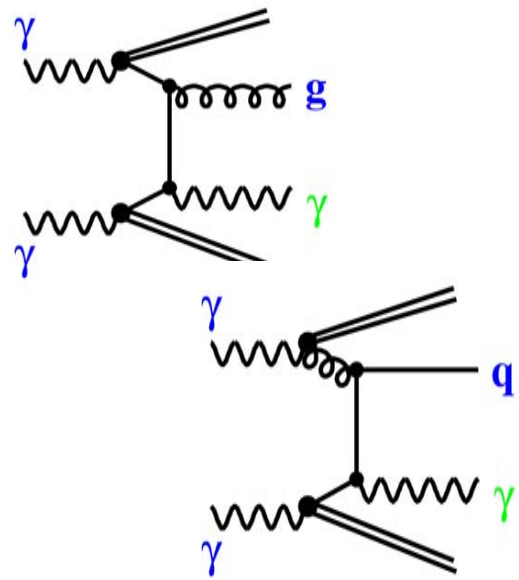
Theoretical Predictions

- Fixed-order NLO QCD calculations (Fontannaz et al).
- PYTHIA 6.130 for signal $\gamma\gamma \rightarrow \gamma + X$
  - Distinct samples for single/double resolved for three energy points.
  - Sas-1D (LO) γ PDF.
- Background with fake / real γ:
  - PHOJET 1.10 and HERWIG 5.9 for $\gamma\gamma$ background without prompt γ.
  - Also Vermaseren 1.0, PYTHIA 5.7, KORALZ, grc4f.

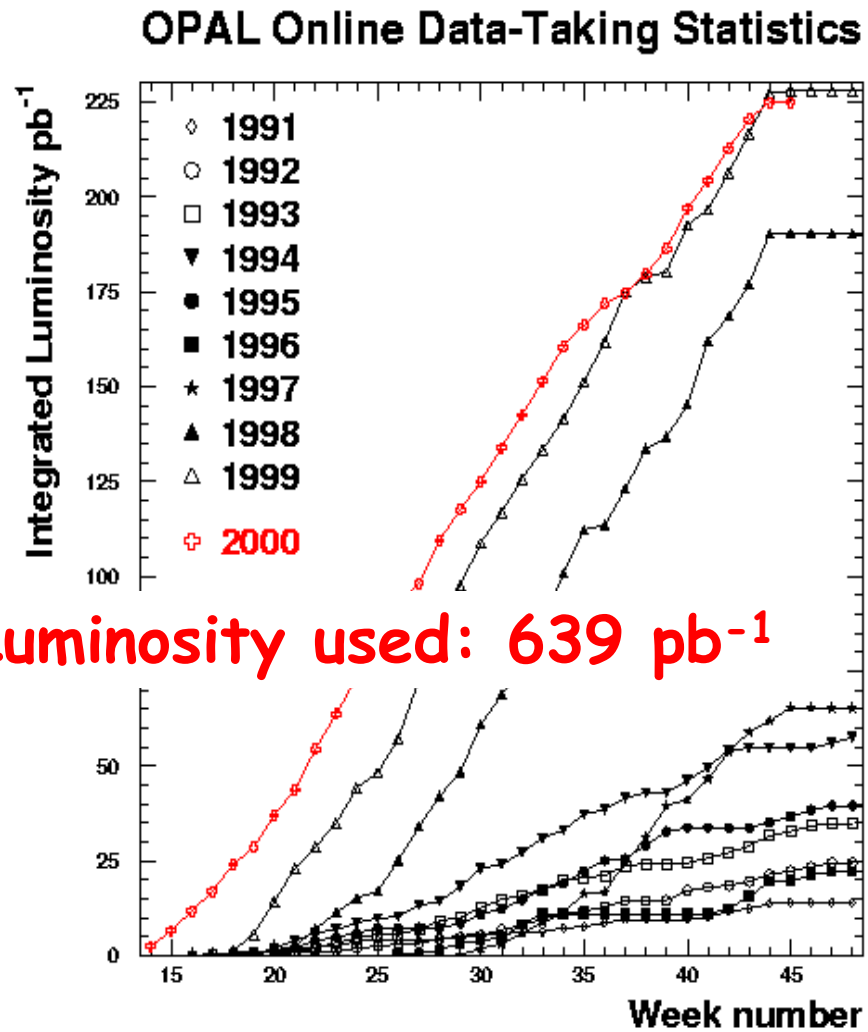
Single-resolved



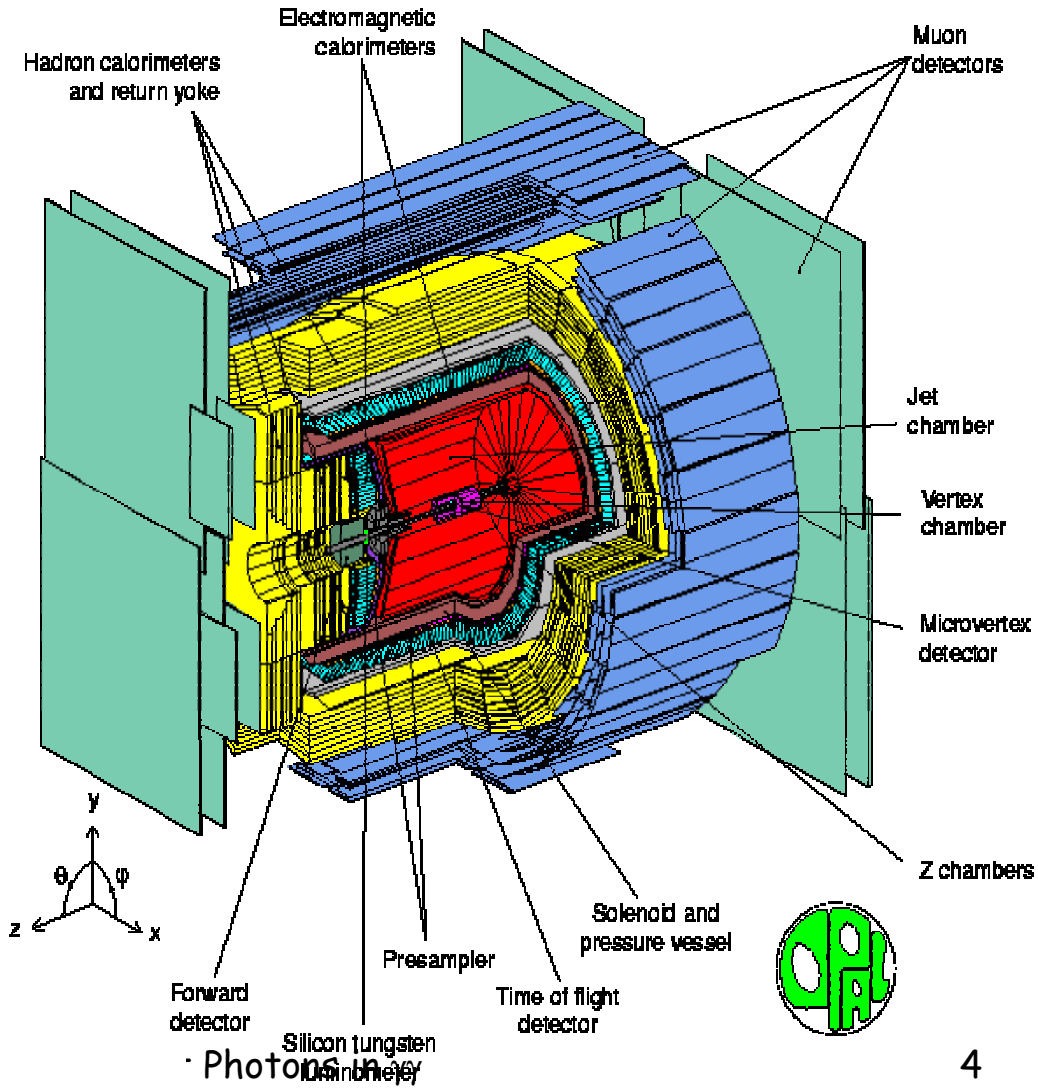
Double-resolved



LEP and the OPAL Detector



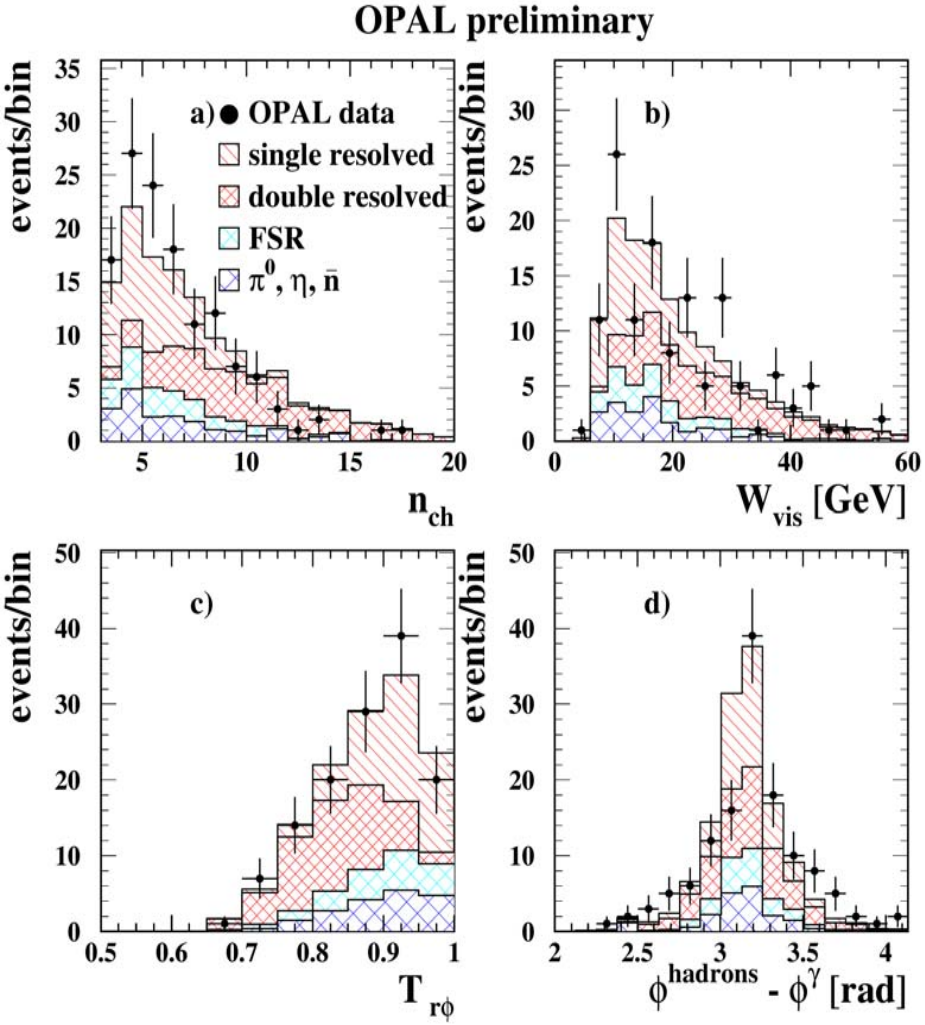
Luminosity used: 639 pb^{-1}



- Photons in ...

Event/γ Selection ($\sqrt{s_{ee}}$=183-209 GeV)

- Require $\geq$3 tracks. Reject events with scattered leptons above θ=33 mrad.
- Reject e+e- annihilations:
  - 5 GeV < W_{vis} < 0.3$\sqrt{s_{ee}}$
  - E_{cal} < 0.25$\sqrt{s_{ee}}$.
- Select isolated photons:
  - EM clusters with $|\eta|$ < 1 and p_T > 3 GeV.
  - Photon and hadronic final state balanced in φ.



Photon Selection ctd'

- Isolation criterion (δ<R):

  $\Sigma_i E_{Ti} \cdot \Theta(\delta - R_{i\gamma}) \leq$
  $0.2 \cdot E_{T\gamma}(1-\cos\delta)/(1-\cos R)$

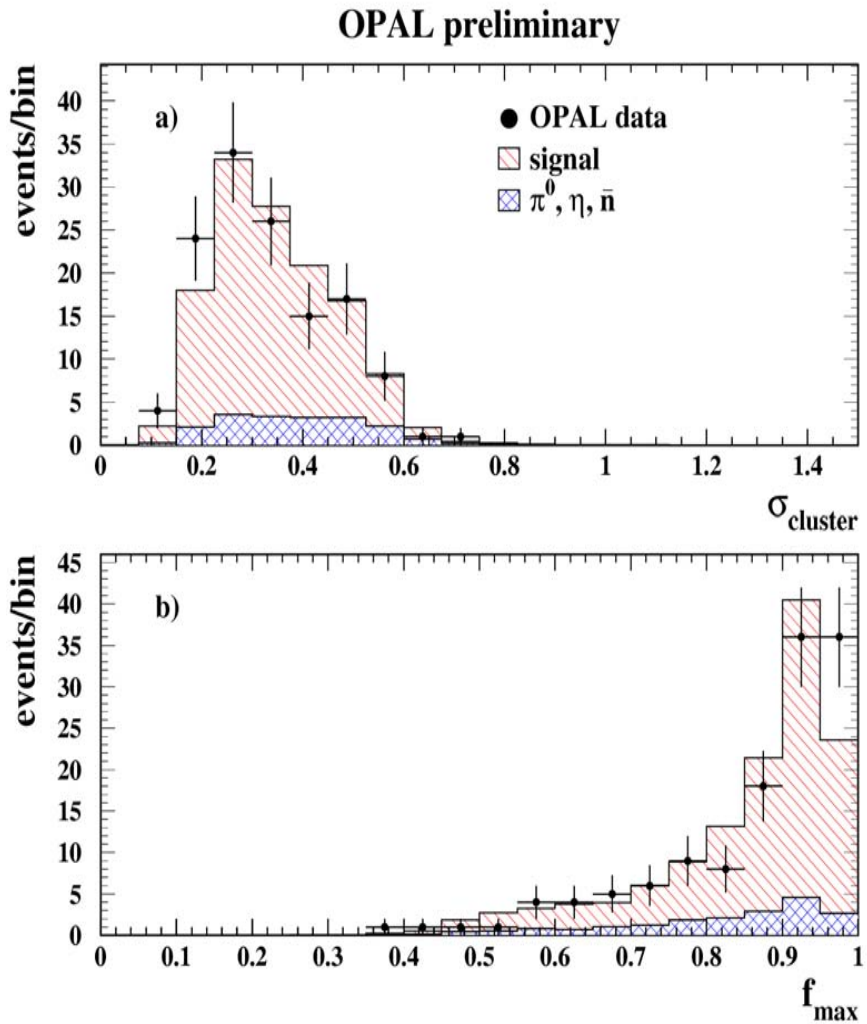
- Background: antineutrons, η/π^0 decays → shape analysis:

  $f_{max} = E_{max}/E_\gamma$

  $\sigma_c = (\Sigma_i E_i R_{i\gamma})/E_\gamma$

  $g(f, \sigma) = a g^\gamma + b g^\pi +$
  $(1-a-b)\cdot(c g^n + (1-c) g^\eta)$

- Fit: a = 0.85 ± 0.08 (stat)
  b = 0.11 ± 0.08 (stat)

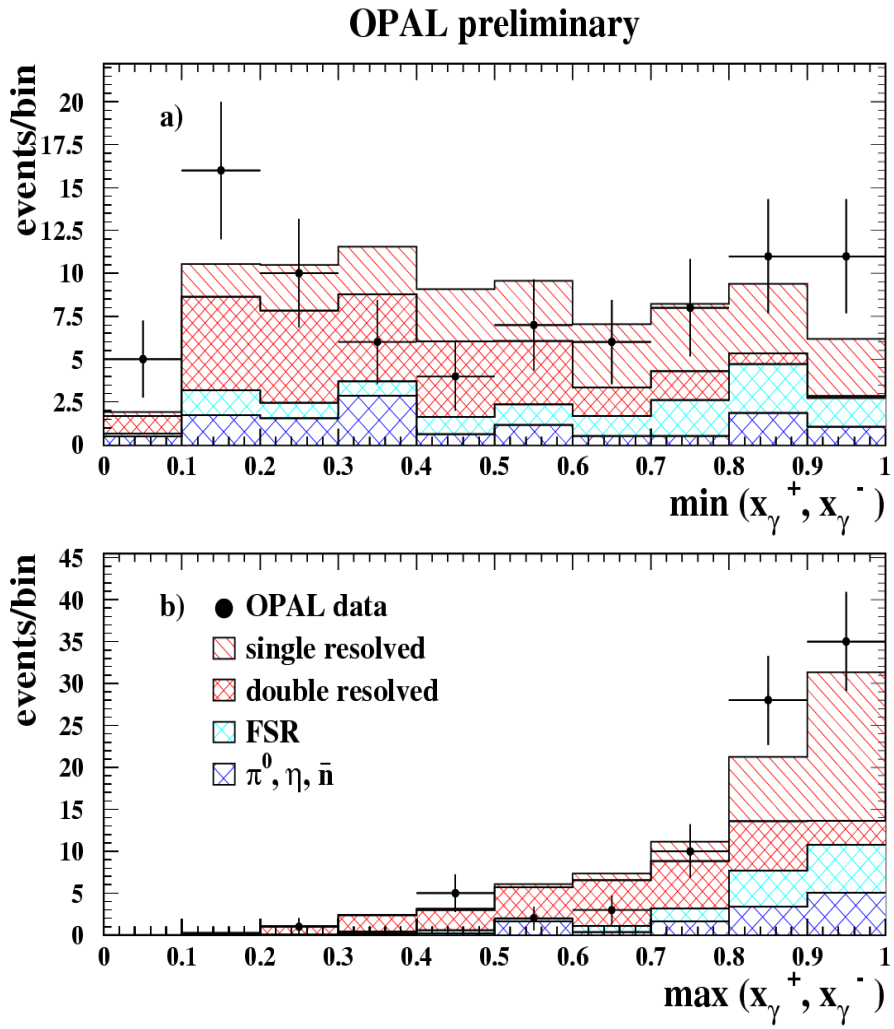


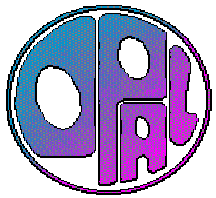
Single/Double Resolved Ratio $r_{s/d}$

- For the γ +jet sample:

$$x_\gamma^{\pm} = \frac{(E_\gamma \pm p_{z\gamma}) + (E_{jet} \pm p_{zjet})}{\Sigma_{hadrons,\gamma}(E \pm p_z)}$$

  using a cone jet finder with R=1, E_T > 3 GeV.
- Fit x_γ^{min} distribution to data → $r_{s/d}$ = 0.59 ± 0.12
- For the complete data set use also $x_T = 2p_T^\gamma / W_{vis}$ → $r_{s/d}$ = 0.41 ± 0.08,
- Average → $r_{s/d}$~0.5.





The Total Cross-Section

For isolated prompt photons ($p_T > 3$ GeV, $|\eta^\gamma| < 1$):

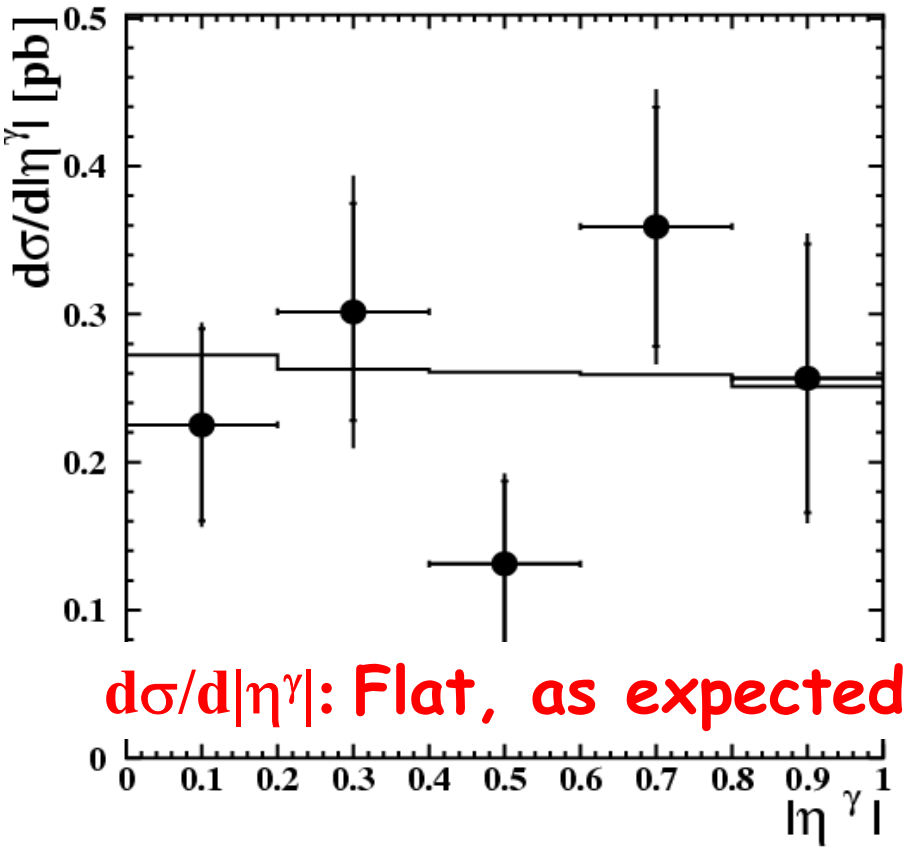
$$\sigma_{tot} = r \cdot N_{prompt}/\varepsilon_{single}L + (1-r) \cdot N_{prompt}/\varepsilon_{double}L$$

- N_{prompt}: 92.8, background subtracted (FSR, π, η, n).
- $r_{s/d}$: single / double resolved ratio.
- ε: Taken from PYTHIA MC (0.51 / 0.61).

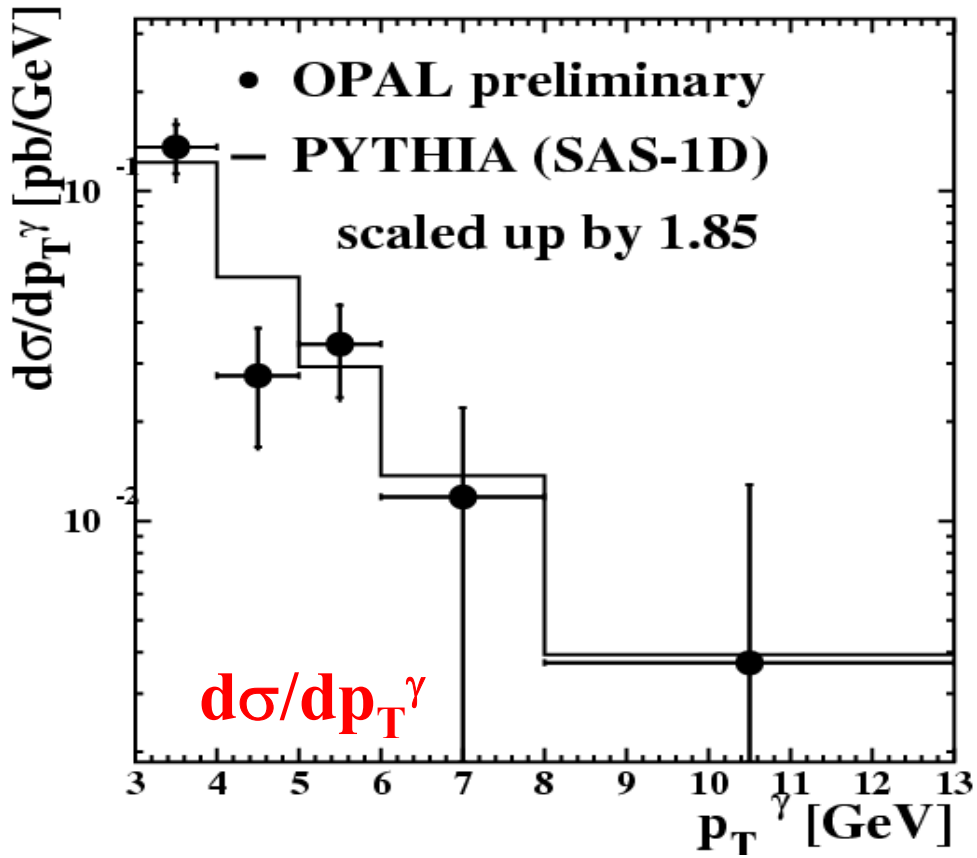
$$\sigma_{tot} = 0.26 \pm 0.04\ (stat.) \pm 0.03\ (syst.)\ pb$$

- Tristan: $\sigma(p_T > 2GeV) = 1.72 \pm 0.67$ pb at $\sqrt{s_{ee}} = 58$ GeV

Comparisons with PYTHIA



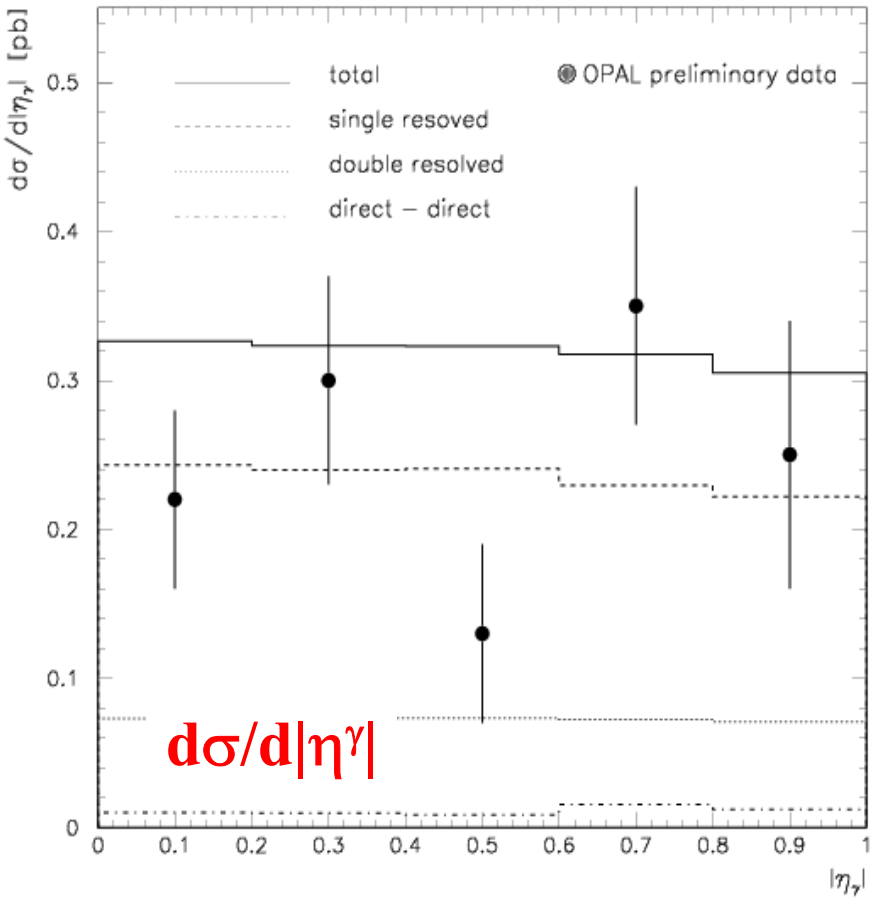
dσ/d|η^γ|: Flat, as expected!

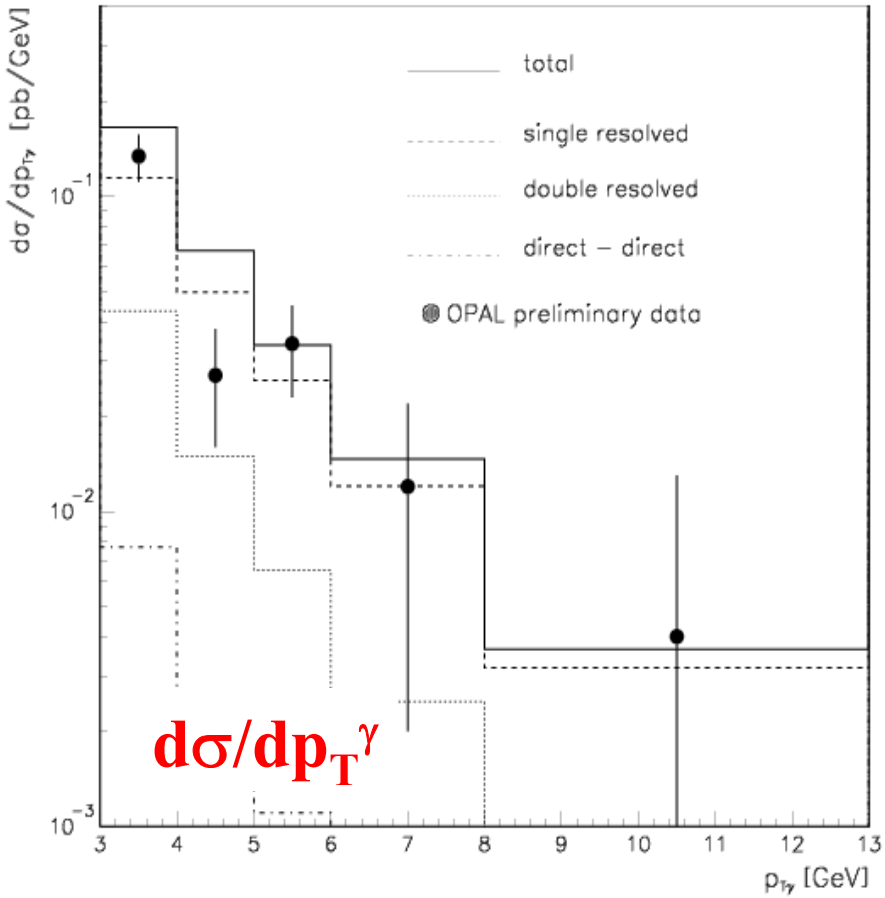


dσ/dp$_T^\gamma$

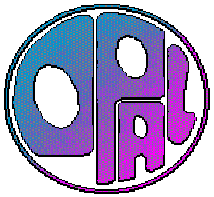
→ Shape of distributions well described, but normalisation off (1.85; in case of TOPAZ ~3, MC also low for ZEUS)

Comparisons with NLO Calculations





- Shape and normalisation correct (Fontannaz et al)!



Summary

- Prompt photons provide means to test QCD and to determine hadronic structure of photon.

  $\sigma = 0.26 \pm 0.04\ (\text{stat.}) \pm 0.03\ (\text{syst.})\ \text{pb}$

- PYTHIA badly normalized; good agreement of differential cross-sections with NLO QCD calculations.
- Looking forward to final result:
  - Test of different photon PDFs (GRV, LAC1).
  - Investigate including FSR in signal → better NLO description?
