

Consequences of t-channel unitarity for pp , γp and $\gamma\gamma$ cross sections at $Q^2 = 0$ and in DIS

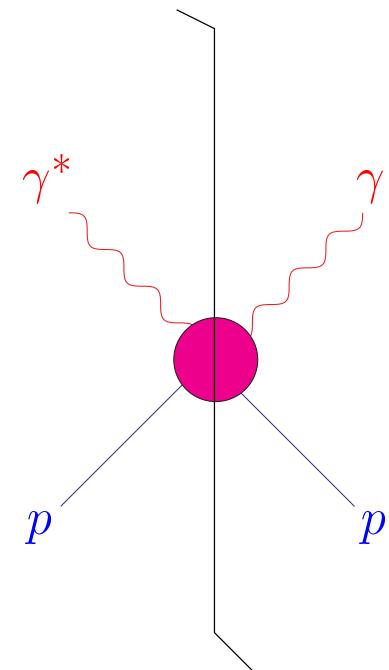

hep-ph/0207196

J.R. Cudell, E. Martynov and G. Soyez
Université de Liège

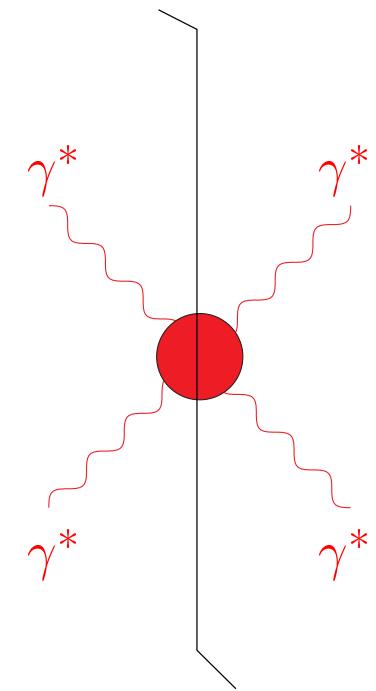

$$\sigma_{tot}^{pp}$$

RHIC: pp2pp

$$\begin{aligned} \sigma_{tot}^{\gamma p} \\ F_2^p \end{aligned}$$

HERA: H1, ZEUS

$$\begin{aligned} \sigma_{tot}^{\gamma\gamma} \\ F_2^\gamma \end{aligned}$$

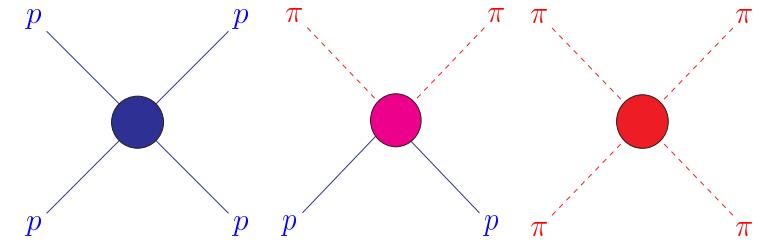

LEP: L3, OPAL

Standard argument: p and π

Go above threshold in the crossed channel: $t > 4m_p^2$

$$S^\dagger S = SS^\dagger = \mathbb{1}$$

$$(S = \mathbb{1} + iT) \implies T - T^\dagger = iT^\dagger T = iTT^\dagger$$

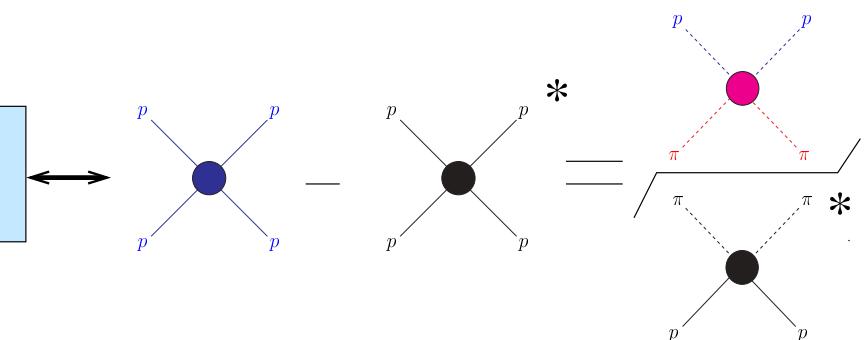

Watson-Sommerfeld transform to complex j plane:

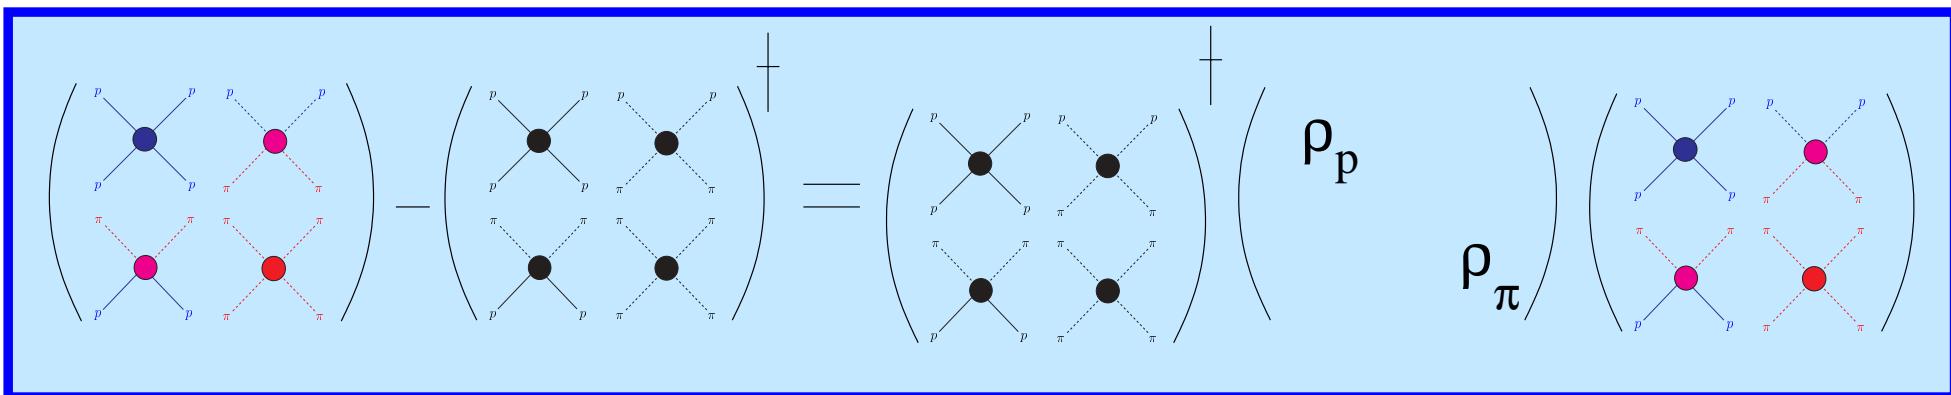

One π threshold:

$$T_{pp}(j, t) - T_{pp}(j, t)^\dagger = T_{p\pi}(j, t)\rho_\pi T_{\pi p}^\dagger(j, t)$$

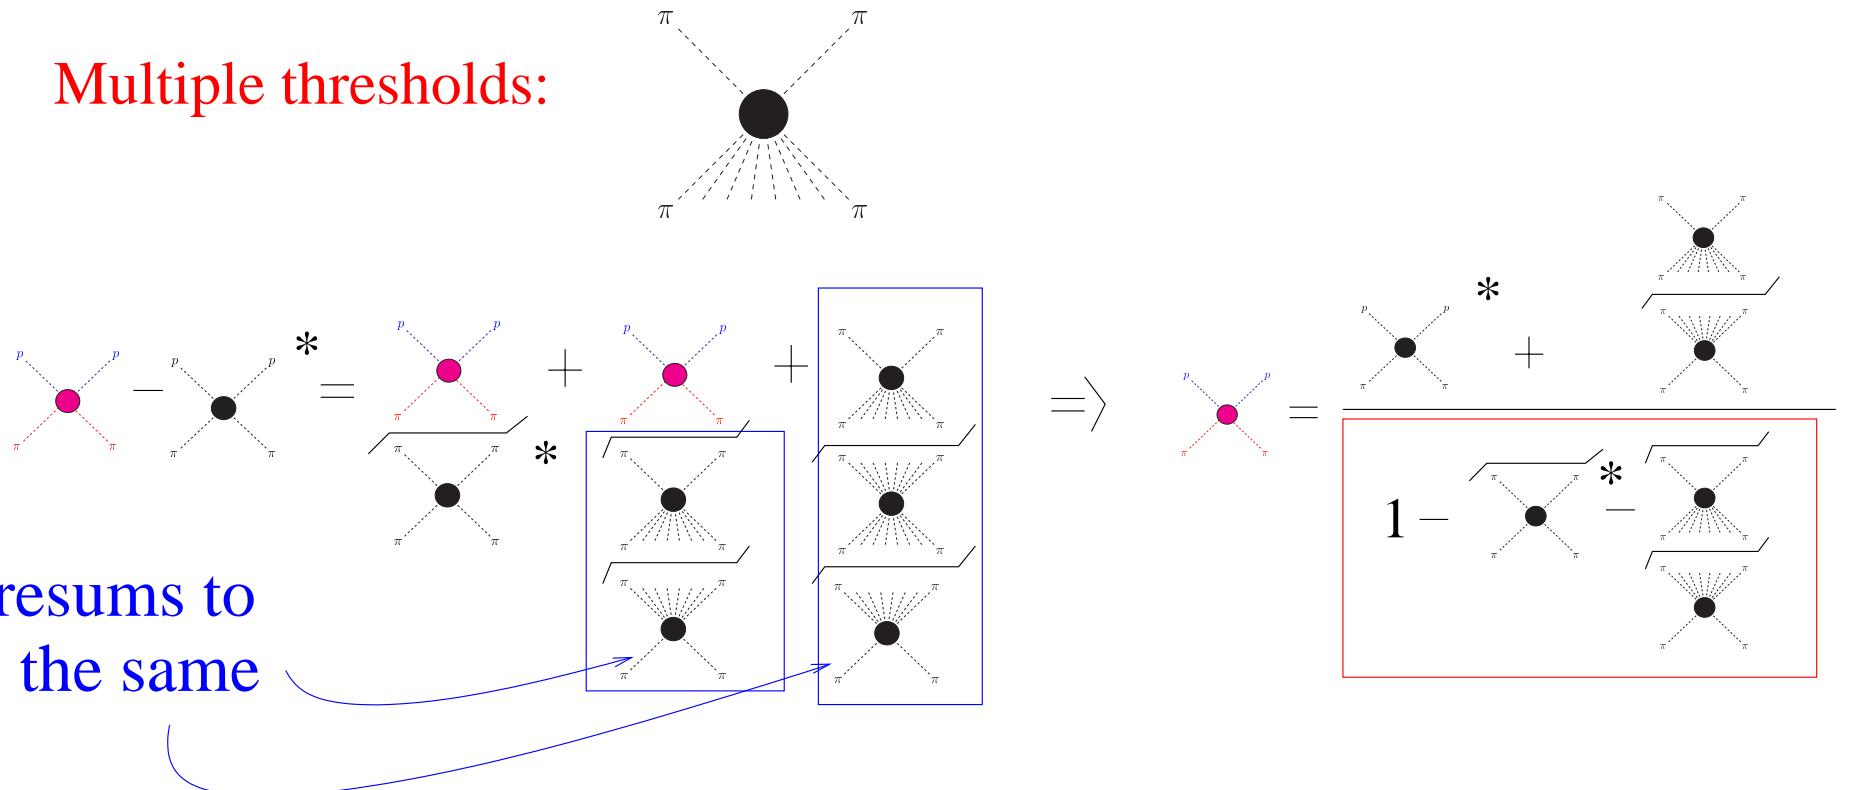

with $\rho_\pi = 2i\sqrt{\frac{t-4m_\pi^2}{t}}$.

p and π thresholds:

Multiple thresholds:

resums to
the same

Multiple thresholds and several processes:

$$\begin{array}{c}
 \left(\begin{array}{c} p \\ p \\ p \\ p \end{array} \right) \times \left(\begin{array}{c} p \\ p \\ p \\ p \end{array} \right) \\
 \left(\begin{array}{c} \pi \\ \pi \\ \pi \\ \pi \end{array} \right) \times \left(\begin{array}{c} \pi \\ \pi \\ \pi \\ \pi \end{array} \right) \\
 \left(\begin{array}{c} p \\ p \\ p \\ p \end{array} \right) \times \left(\begin{array}{c} p \\ p \\ p \\ p \end{array} \right) \\
 \left(\begin{array}{c} \pi \\ \pi \\ \pi \\ \pi \end{array} \right) \times \left(\begin{array}{c} \pi \\ \pi \\ \pi \\ \pi \end{array} \right)
 \end{array} = \boxed{1 - \begin{pmatrix} \rho_p & \\ & \rho_\pi \end{pmatrix} M}$$

M

D

- All amplitudes have the same singularities
- They come from the zeroes of $\det(D) = \Delta$
- Factorisation:

$$\left(\begin{array}{c} p \\ p \\ p \\ p \end{array} \right) \times \left(\begin{array}{c} \pi \\ \pi \\ \pi \\ \pi \end{array} \right) = \left(\begin{array}{c} p \\ \pi \\ p \\ p \end{array} \right) \times \left(\begin{array}{c} p \\ \pi \\ p \\ p \end{array} \right) + O(1/\Delta)$$

● Factorisation:

$$\begin{array}{c} p \\ \diagup \quad \diagdown \\ \bullet \end{array} \quad \begin{array}{c} \pi \\ \diagup \quad \diagdown \\ \bullet \end{array} = \begin{array}{c} p \\ \diagup \quad \diagdown \\ \bullet \end{array} + \begin{array}{c} \pi \\ \diagup \quad \diagdown \\ \bullet \end{array} + O(1/\Delta)$$

$$\lim_{j \rightarrow z_m} \left[T_{\pi\pi}(j) - \frac{T_{p\pi}(j)T_{\pi p}(j)}{T_{pp}(j)} \right] = \text{finite terms.}$$

complex j-plane for t>0

relations for residues of each singularity
 → continue to t<0

Simple poles

$$T_{pq} = \frac{S_{pq}}{j - z}$$

$$\Downarrow$$

$$S_{22}S_{11} = (S_{12})^2$$

Simple and double poles

$$T_{pq} = \frac{S_{pq}}{j - z} + \frac{D_{pq}}{(j - z)^2}$$

$$\Downarrow$$

$$\boxed{\begin{aligned} D_{11}D_{22} &= (D_{12})^2 \\ D_{11}^2S_{22} &= D_{12}(2S_{12}D_{11} - S_{11}D_{12}) \end{aligned}}$$

New tCU relations

Simple, double and triple poles

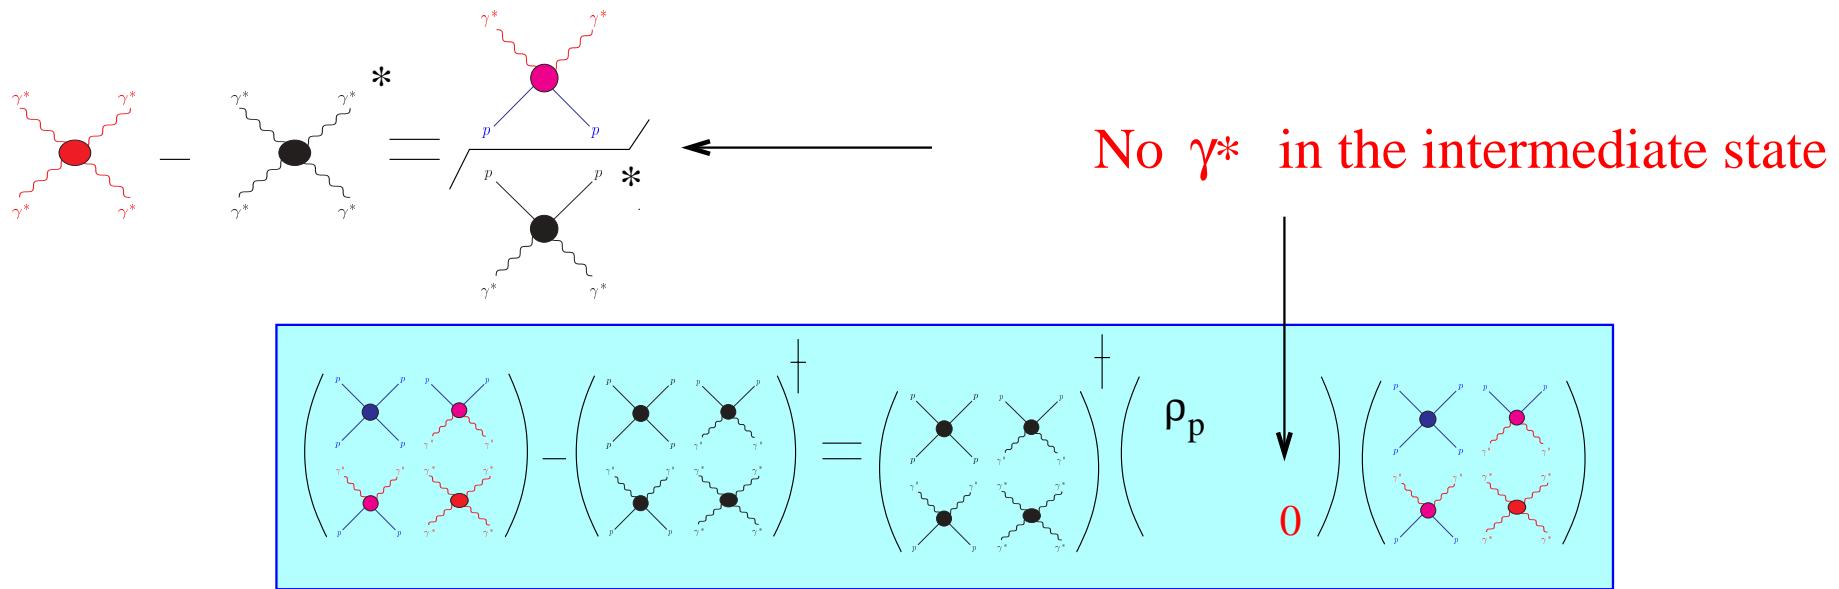

$$T_{pq} = \frac{S_{pq}}{j - z} + \frac{D_{pq}}{(j - z)^2} + \frac{F_{pq}}{(j - z)^3}$$

$$\Downarrow$$

$$F_{11}F_{22} = (F_{12})^2$$

$$\boxed{\begin{aligned} F_{11}^2D_{22} &= F_{12}(2D_{12}F_{11} - D_{11}F_{12}) \\ F_{11}^3S_{22} &= F_{11}F_{12}(2S_{12}F_{11} - S_{11}F_{12}) \\ &+ D_{12}F_{11}(D_{12}F_{11} - 2D_{11}F_{12}) \\ &+ D_{11}^2F_{12}^2 \end{aligned}}$$

The case of off-shell photons

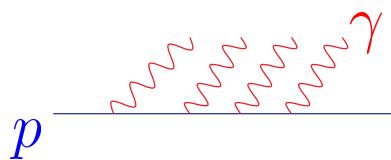

Several channels, multiple thresholds...

$$\begin{aligned}
 & \text{Diagram with 4 blue lines } p = \frac{M}{D} \quad \text{Same as before} \\
 & \text{Diagram with 4 blue lines } p \text{ and 2 red wavy lines } \gamma^* = \frac{N}{D} \quad \text{Possible new singularities} \\
 & \quad \text{additionally to the old ones} \\
 & \text{Diagram with 4 red wavy lines } \gamma^* = \frac{N^2}{D} + N' \quad \gamma^* p \text{ singularities squared} \\
 & \quad \text{New (purely perturbative?) singularities}
 \end{aligned}$$

The case of on-shell photons

Problem:

Soft emissions may destroy the possibility
to define exclusive processeses
no S matrix for QED

- ⇒ photons do not enter the tCU relations
- ⇒ on-shell photons can have extra singularities, as off-shell photons

Remarks:

Existence of a pole mass for the electron?

Possibility of collective states?

cfr Lavelle, Mc Mullan, Bagan et al.

The existence of extra singularities in photon total cross sections
would prove that one cannot recover an S-matrix formalism in QED

Models for σ

lower trajectories: a/f

$$Y(Q^2)(2\nu)^{-\eta}$$

rising term

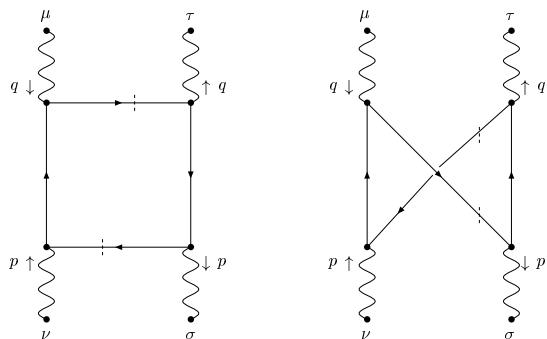

double pole

$$\begin{aligned} D(Q^2) \left[\log \left(1 + \Lambda(Q^2)(2\nu)^\delta \right) \right. \\ \left. + (s \rightarrow u) \right] \\ + C(Q^2) \end{aligned}$$

triple pole

$$\begin{aligned} t(Q^2) \left[\log(2\nu) + d(Q^2) \right]^2 \\ + c(Q^2) \end{aligned}$$

box diagram

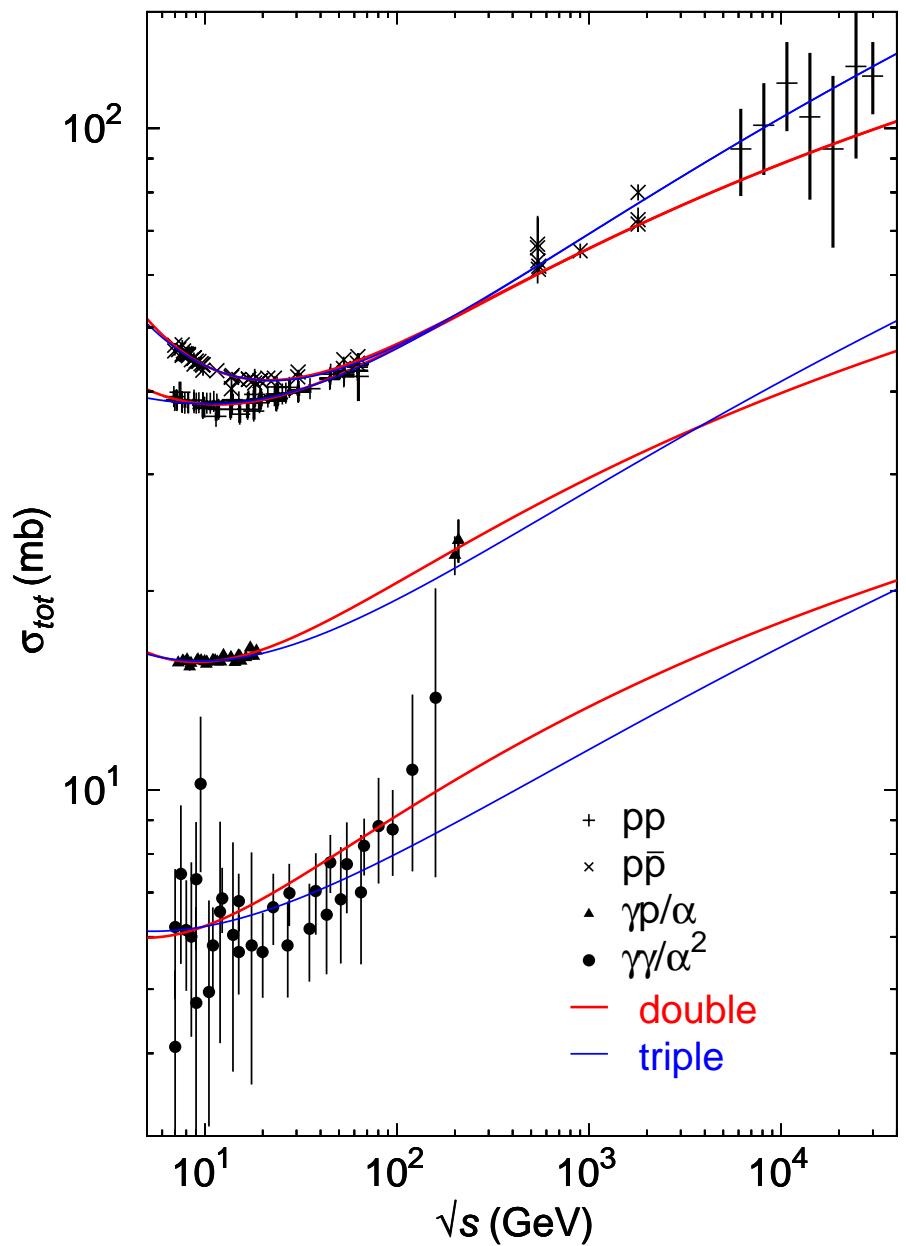

only for off-shell photons

Fit to total cross sections:

from 7 GeV to 30 TeV

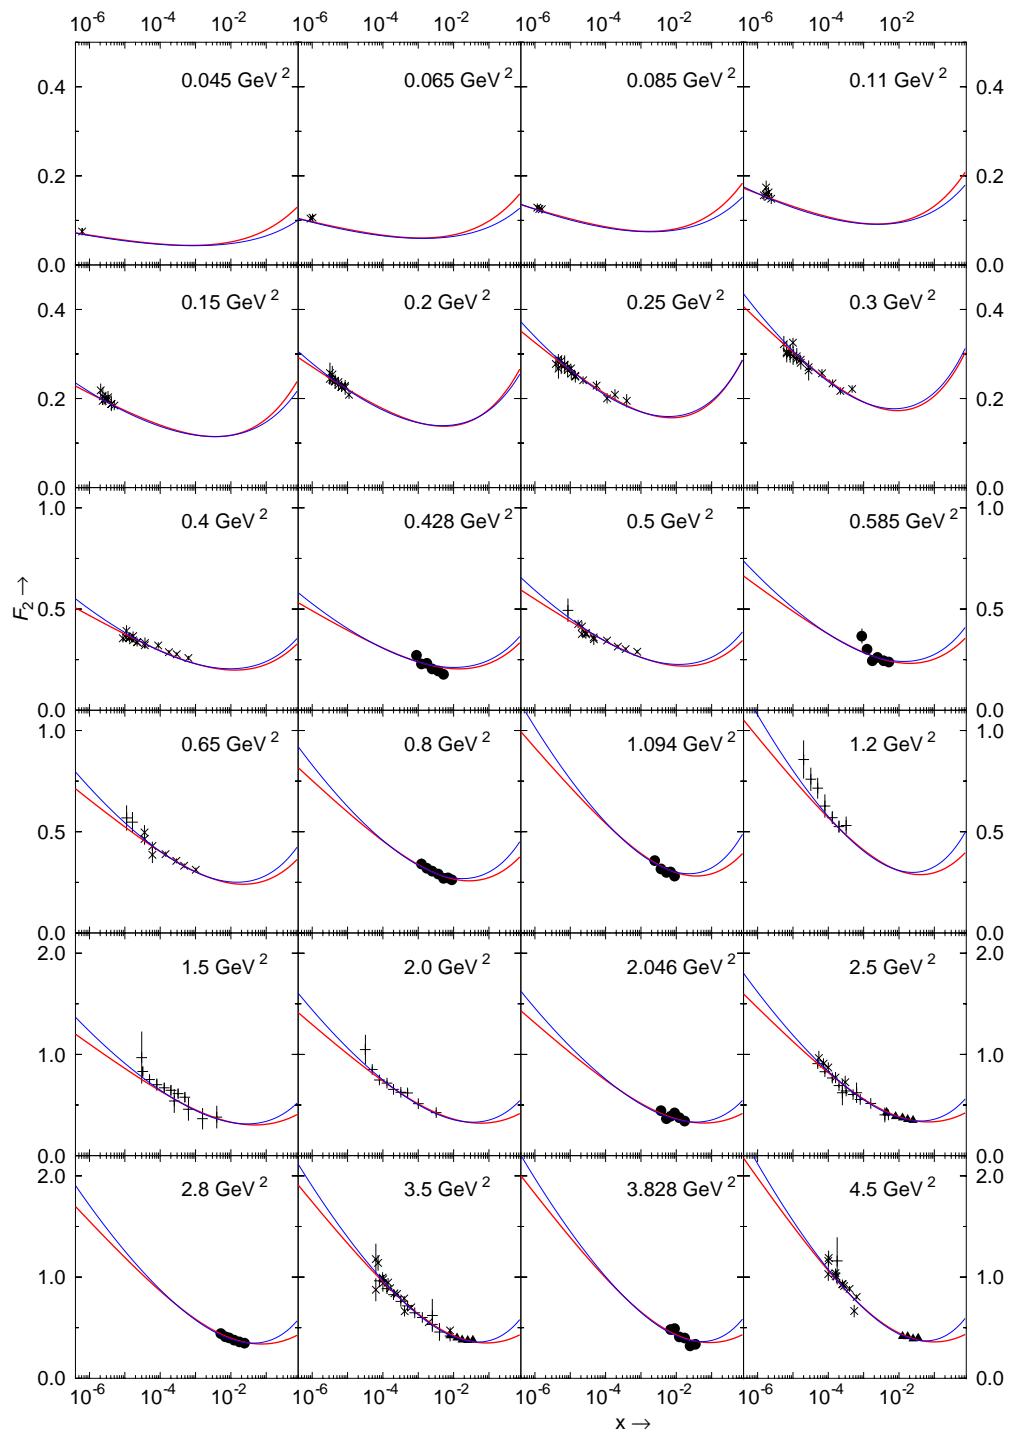

γ down to 2 GeV!

low side of error bars

no box diagram contribution

no extra singularities

F_2^p at low Q^2

$$x < 0.3$$

$$Q^2 < 400 \text{ GeV}^2$$

$$2\nu > 7 \text{ GeV}^2$$

$$|\cos(\vartheta_t)| = \frac{\nu}{m_p \sqrt{Q^2}} > \frac{49}{2m_p^2}$$

good fit to all data

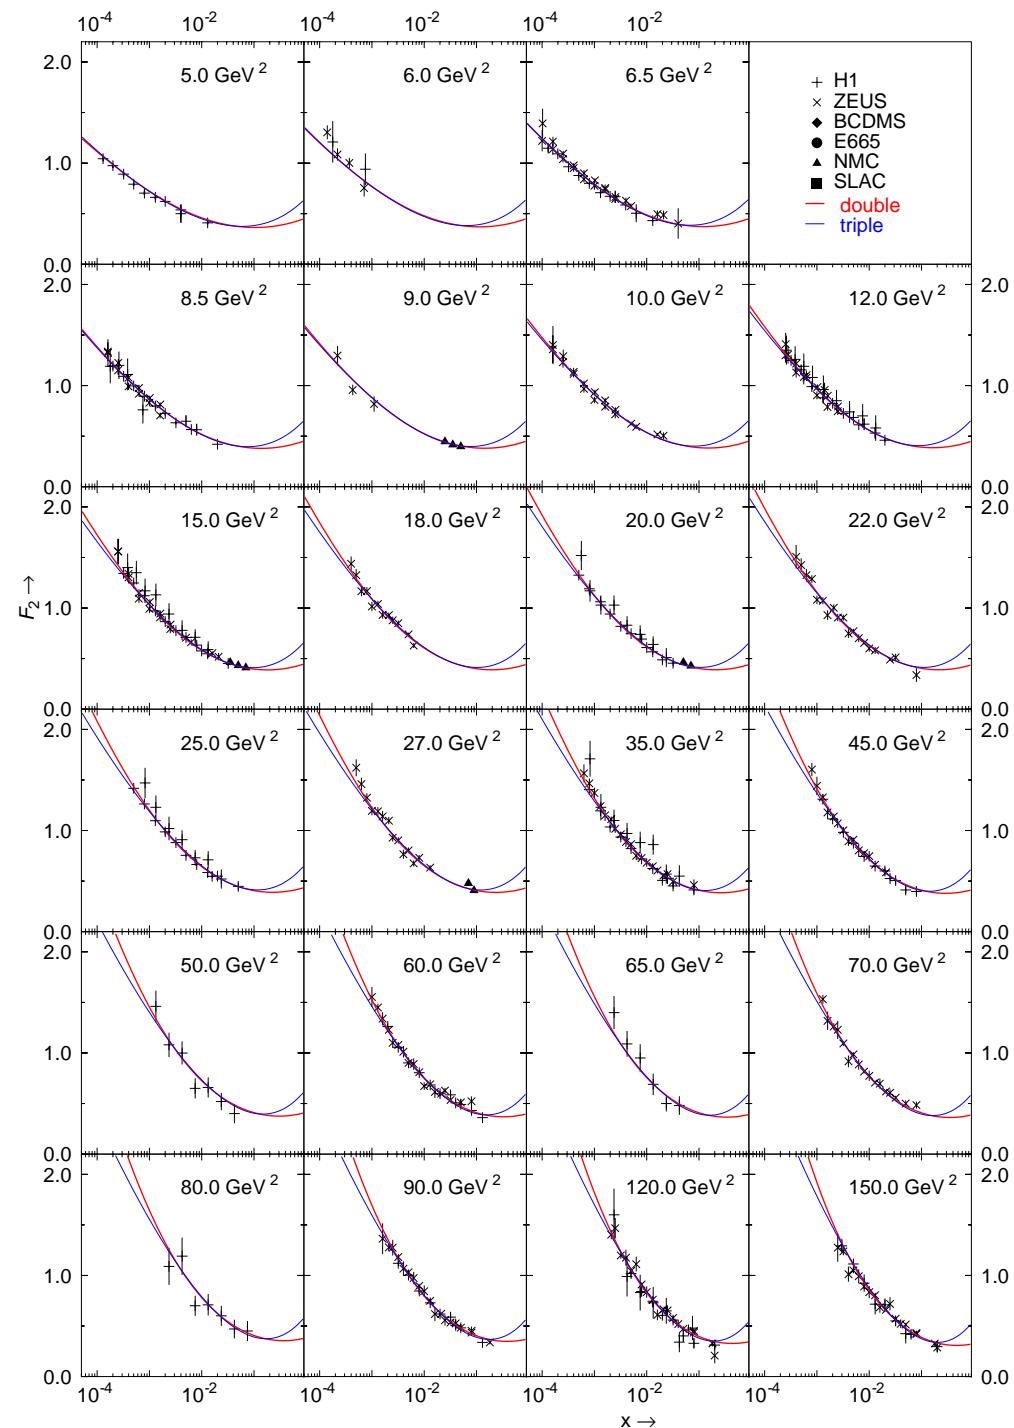

extrapolates to "low"
total cross sections

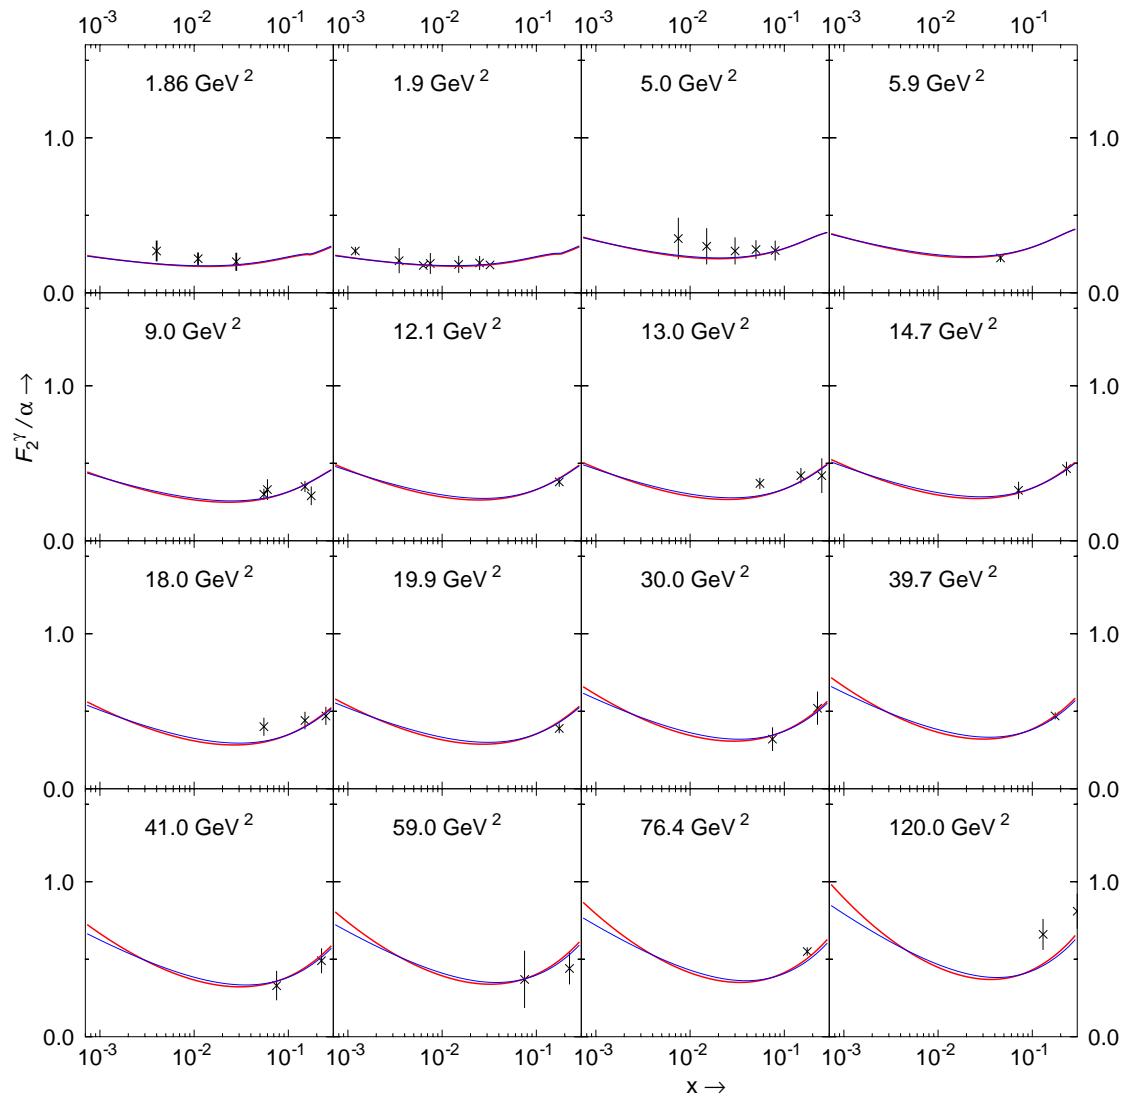

F_2^p at higher Q^2

$x < 0.3$
 $Q^2 < 400 \text{ GeV}^2$
 $2\nu > 7 \text{ GeV}^2$
 $|\cos(\vartheta_t)| = \frac{\nu}{m_p \sqrt{Q^2}} > \frac{49}{2m_p^2}$

no hard pomeron

no DGLAP evolution

F_2^γ

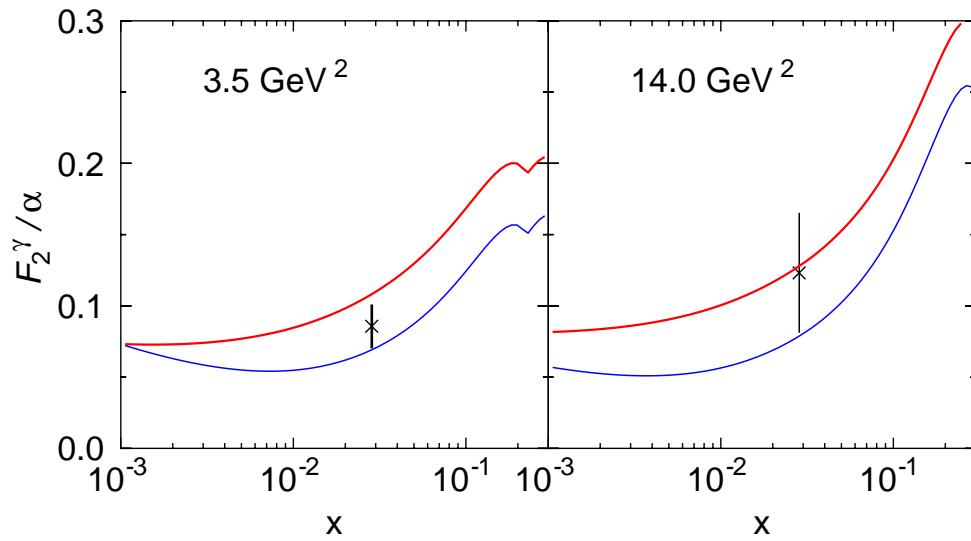

$$\begin{aligned} & x < 0.3 \\ & Q^2 < 800 \text{ GeV}^2 \\ & 2\nu > 7 \text{ GeV}^2 \\ & |\cos(\vartheta_t)| = \frac{\nu}{Q^2} > \frac{49}{2m_p^2} \end{aligned}$$

test of tCU relations

good fit to all data

need box diagram

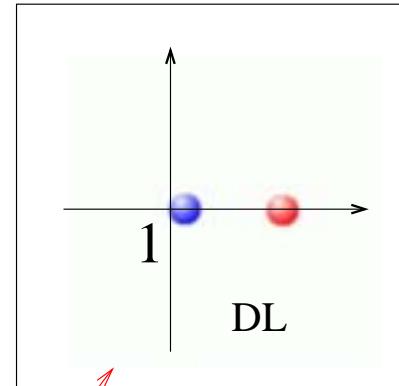

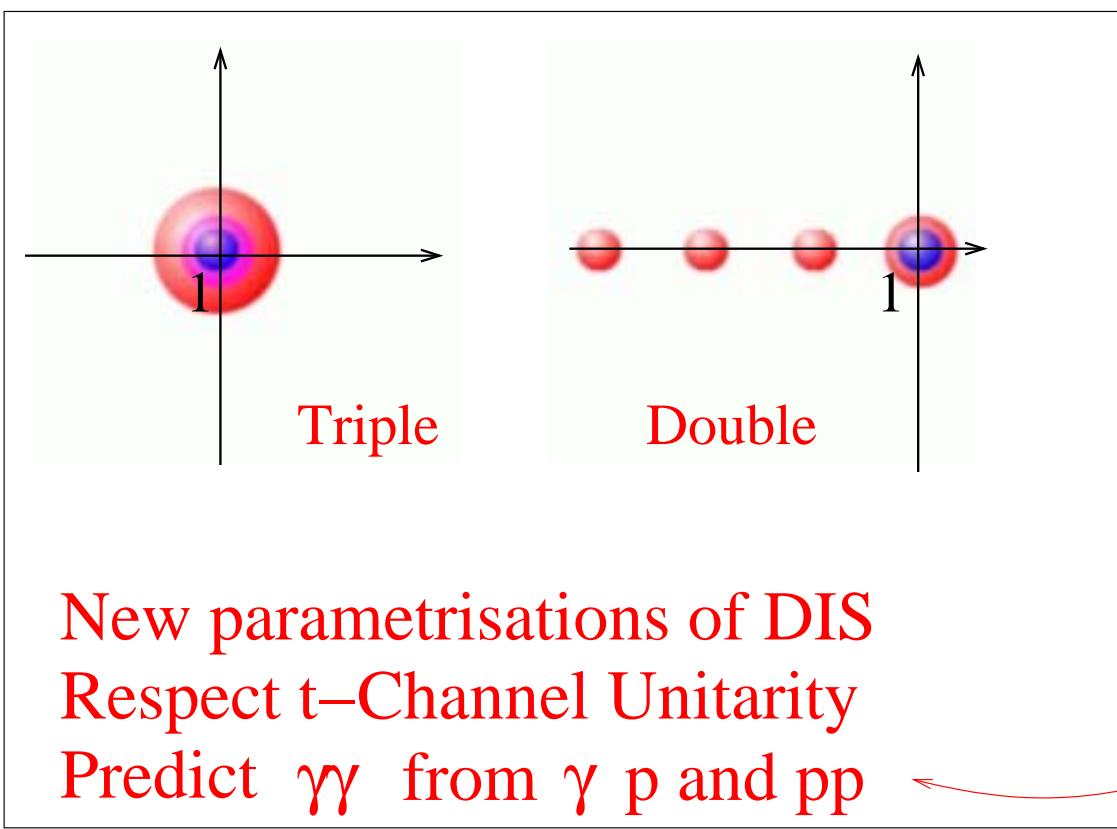

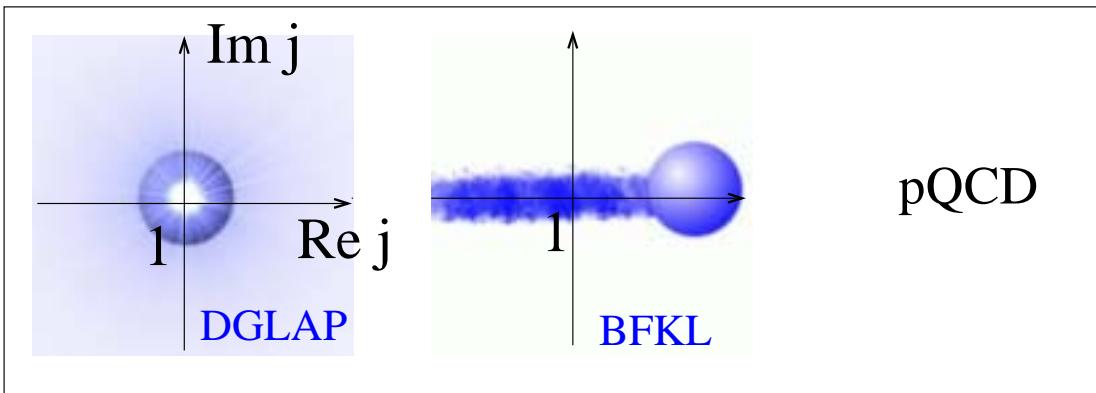

F_2^γ : perturbative (BFKL) region

The soft fit + the box diagram seem to be sufficient
to reproduce the data

Note: this can be done directly using the tCU relations and HERA data

Conclusion: singularities at $t=0$
